THE

PHOTOGRAPHIC NEWS:

WEEKLY RECORD

OF THE

PROGRESS OF PHOTOGRAPHY.

VOLUME XXIII.

EDITED BY G. WHARTON SIMPSON, M.A., F.S.A.

Nulla recordanti lux est ingrata.—MARTIAL.

LONDON:
PRINTED AND PUBLISHED BY PIPER AND CARTER,
5, CASTLE STREET, HOLBORN, LONDON, E.C.

1879.

LONDON:

PIPER AND CARTER, PRINTERS, CASTLE STREET HOLBORN, E.C.

P R E F A C E .

THE Volume of the PHOTOGRAPHIC NEWS just completed is, like those which have preceded it, a chronicle of twelve months' research, experiment, and result—a chronicle, in fact, of a year's work in photography throughout the world. But, unlike all others, it is chiefly devoted to the history of a revolution. The twelve months have witnessed a greater change in the practice of the art than has been seen by any former period. A dry process, far outstripping any preceding process in rapidity, has been quietly superseding the wet collodion process, in the studio as in the field, and bids fair to come into general practice. The gelatino-bromide process has met with almost universal acceptance.

The Volume which these words close contains a history of the experiences and the practice of this new outcome of the art, and will prove an invaluable text-book and guide in all matters of detail concerning it. The Editor wishes to all those who have contributed by their communications to make the Volume such a guide, as well as to all correspondents and readers, a Happy New Year.

Christmas, 1879.

The Photographic News, January 3, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO HIGH PRICES AND GOOD WORK IN PHOTOGRAPHIC POR- TRAITURE.—A NEW PROPERTY OF GELATINE.

High Prices and Good Work in Photographic Portraiture.—The price at which photographic portraits are sold on the Continent is naturally a subject of interest with photographers at home, and it is with considerable satisfaction that we learn from correspondence in our columns that high prices are still in vogue with us. Good work and good pay are always so closely connected that unless fair prices are asked, we naturally question the quality of the work. A sovereign for a dozen carte-de-visite portraits is no very large sum to pay for the best highly finished work, but of course the public will not give this amount for ordinary photographs which have no novelty of particular excellence to recommend them. We in England, there is no doubt, have a tendency to "rest and be thankful," in the matter of photographic portraits, as in other matters, and we are imitators rather than initiators. After the first Parisian and Viennese portraitists have adopted a style or format, we steadily follow suit and produce the same. This would not so much matter if Englishmen of the well-to-do classes were not travellers, and did not run over to the Continent once a year; but as such is the case, the styles are no longer novelties by the time we adopt them. "I saw that a year ago on the Boulevards or in the Graben," will be the reply under the circumstances. The only novelty of importance among the exhibits in the Paris International Exhibition—we mean in the French photographic section—were the tiny portraits vignettted on a translucent black ground. This style of picture, if it were once adopted in this country, would perhaps command as high a price as in Paris; but two or three years hence it will be different. It was the same with ornamental borders, with glazed enamels, and with the practice of fine retouching. In this country we were a long time introducing these modifications, and when they were once introduced, then everybody adopted them, and they became to a certain extent vulgarised, although, by the way, it is only a year ago that we were shown by a Dublin photographer a glazed *bombe* portrait by way of novelty, such as have been produced in Vienna for the past five years and more. The Denier photographs, again, so sharp and yet so exquisitely soft, although it has been asserted again and again that the effect was easily produced by printing with two films, have never been equalled in this country. Another Russian, Bergamasco, whose high class work has always been well paid, affords a further instance that photographers abroad, if they are successful, are quite deserving of their success. It is either that they have novelty or very good work to sell, and though they ask high prices they get them. It is very certain that unless they do receive good pay, they could never turn out such work. Everybody knows what a mere selection of prints will do. Let a series be ever so carefully toned and printed, you have no difficulty in selecting the best dozen out of twenty, and if you still further reduce the number to be chosen to six, the prints selected represent a much higher level of work. Therefore, unless high prices are not asked, work of a first-class order cannot be rendered. Finish and perfection cannot be sold for nothing, and if a photographer charges low prices, he must perforce sell an inferior article. Few would say that the first-class work of London and Paris photographers which commands high prices does not testify to the possession on the part of the artist of either originality, or novelty, or exceeding skill.

A New Property of Gelatine.—Gelatine is such a universal agent in photography that any information we can get of its properties is to be valued. Not only in the pigment or carbon process is it employed in very large

quantities, but also in photo-relief printing, and in negative work. Gelatino-bromide plates are already well-known for their keeping qualities and great sensitiveness, the rapid films of Mr. Swan being, we believe, prepared with the aid of gelatine. For this reason, photographers will be glad to know of a new application of gelatine to the preservation of food which has just been made in America. The setting or gelatinizing action of the material is found to exercise great benefits when mixed with liquid foods. Not only does it gelatinize them, and put them into a more portable form, but the gelatine acts as a true preservative. Neither is the mixture of gelatine and liquid so prone to mildew as before. As an instance of what may be done, we may mention that a pound of gelatine can be dissolved in a gallon of milk, and the resulting jelly will keep sweet and good a very long time. The jelly may be cut into strips, and the latter dissolved once more in a second gallon, with similar effect. Nay, more, the operation may be repeated until the original pound of gelatine is contained in no less than ten gallons of milk, which is thereby preserved in a wonderful manner from decomposition. Possibly photographers may see their way clear to employing the gelatine in like manner for preserving substances with which they have to do; but, at any rate, it is well worth their while to note this property of gelatine which has just been discovered. Our readers may remember that it is not the first time the material has been employed in the preservation of food, for the German commissariat used gelatine in the last war very frequently to manufacture cheap waterproof packing. Nay, one of the things that contributed to the success of the famous pea-sausages was gelatine added to another photographic requisite, bichromate of potash. By having recourse to this mixture, the costly skins hitherto employed for this packing were unnecessary. The sausage, a mixture of pea-meal and bacon fat, properly seasoned, was in universal request for the German army, since it formed at once a diet complete in itself, and one which was easily transported and distributed. Issued ready cooked, the soldier was able to eat it cold as he received it, or might make it into soup or stew. The supply of skins was altogether inadequate to the demand, and the price of these rose enormously with the scarcity. Indeed this want was at one time on the point of putting an end to the manufacture of the convenient food. Waxed cloth or greased linen permitted the fat to permeate through the interstices, and parchment paper was found to be equally unsuitable for packing the pea-meal mixture and resisting the operation of boiling. In this dilemma the employment of gelatine and bichromate was suggested. The sausage material was pressed into shapes of the most desirable form, and these were then dipped first in gelatine, and then into a solution of bichromate of potash. A skin was thus produced which, when dried and exposed to daylight, afforded a stout resistant, and at the same time as expanding a covering as that afforded by gut skin. In a word, the sausages were covered with a sensitive film and photographed. The same process is made use of sometimes by builders for waterproofing walls. Bichromate of potash solution is added to warm size, and this is then applied to a wall in the ordinary manner. The coating dries, and as the daylight acts upon it the surfaces gradually get photographed, and at the same time hard and waterproof. In all cases where a yielding waterproof material is desired, bichromated gelatine may be employed, and we doubt not but what it might be substituted in many ways for the expensive marine glue in daily use by mechanics and engineers.

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

The following table gives the results obtained by the

* Continued from page 699, vol. xxii.

above methods with different kinds of gelatine and glue:—

KINDS OF GELATINE.	Percentage of water in gelatine dried at 120° C.	Percentage of ash in gelatine air dried.	Parts by weight of water taken up by one part by weight of gelatine at 15° C.	Number of grammes that a ten per cent. solution of gelatine is able to bear.	Number of grammes that a similar solution, to which five per cent. chrome alum has been added, can bear.	Melting point of a ten per cent. solution in degrees C.

Discussing this table, the author explains that the gelatines therein numbered 1, 2, 3, and 4, are manufactured by Messrs. Coignet and Co., of Paris; they are all transparent and colourless with the exception of No. 4, which is yellowish. No. 5 is an excellent gelatine for collotyping; it is used for that purpose by Albert, of Munich. No. 6 he find to be well adapted for carbon printing and photo-electrotyping, and No. 7 for collotypes, but there seems to

be no marked difference between them as regards their fitness for photographic purposes. Nos. 8 and 9 are excellent collotype gelatines, and so are Nos. 10 and 11; the latter are of Paris manufacture. No. 12 is a very good gelatine for the carbon process, as well as for collotype, for which latter purpose it is employed by Obernetter; it is labelled "Manufacture de Gelatine F. F. Creutz, Michelstadt 70, Blane 1st qual." No. 13 is a gelatine made to be used in cooking, though it is also well adapted for collotyping. No. 14 is manufactured by Seitz, and was by him submitted to the notice of the Photographic Society of Vienna, but it is of no use for photographic purposes. Nos. 15 and 16 are ordinary commercial gelatines of fine quality; they can be both, but especially the second, employed in photography. All the above are in the form of thin colourless leaves, which, after soaking, are easily soluble in water; but Nos. 17 to 24 are more or less yellow in colour, and are much more difficult of solution than the former. Nos. 17, 18, and 19 can be neither used in the carbon or collotype processes, and Nos. 20 to 24 are quite useless.

It will be seen that the amount of ash is in each case very small. This ash consists principally of the carbonate and sulphate of lime, besides a small quantity of alumina; traces are also found of phosphoric acid and silica, as well as of the oxides of magnesium and iron, and of the alkaline metals. The composition of the ash is in all cases nearly alike, only the relative amount of lime carbonate and of gypsum vary a little; the latter must not be regarded as adulterations, for they are necessary additions in the course of manufacture.

Alum may sometimes be used for adulterating gelatine, because it increases its consistency and its proneness to gelatinize; but as the addition of this salt deteriorates the quality of the gelatine for photographic purposes, it becomes important to be able to detect it. The addition must amount to at least ten per cent., or it will not produce the desired effect, and in this case it will increase the quantity of ash from six to seven per cent. A quantitative determination of the ash in any sample of gelatine is therefore at once sufficient to detect an adulteration with alum.

(To be continued).

THE POISONOUS NATURE OF CHROMIC SALTS.

BY M. DUCHOCHOIS.*

MR. PRESIDENT: I have the pleasure this evening of calling the attention of photographers to the poisonous properties of the bichromate used in the carbon and other photographic processes. When they were introduced in this country, most every one thought that the action of chromic acid was similar to that of sulphuric, nitric, and such acids, that disorganize the tissues only on the parts they have been in contact with. Unfortunately, for many of us, the danger is much greater. Not only a local disorganization takes place, but, by absorption into the system, this acid originates a disease of the skin, spreading to every part of the body, for which there is no sure remedy known.

I am one of the sufferers from the omission of the sellers of the carbon process patents, who in their oral, printed, or published instructions, did not caution anyone even by a single hint, against the terrible consequences of handling the bichromate solutions without extreme care.† My case has been a very serious one. The skin of the hands, on which at first appeared small itching vesicles, split and fell out in scales, leaving the flesh bare and unannulated. The disease extended to the interior of the nose, under the eyes, the feet; in fact, to all parts of the body. The lungs were also affected, and after eight months there is still some dis-

* Read before the Photographic Section of the American Institute.

† Very early after the use of chromic salts came into something like general use, we devoted articles to pointing out the poisonous nature of these salts, both when taken internally and by absorption, and in our work on Pigment Printing, published in America by Anthony and Co., we devoted a chapter to this subject.—Ed. P. N.

order in the vital organs. I have been many weeks without being able to help myself, and the disease, now in its chronic stage, is far from being cured.

Shall it be concluded from these comments that the carbon process should be discarded? Not at all! I would be sorry to discourage anyone from working this beautiful process. But it must be constantly borne in mind that the greatest care must be taken not to let the bichromate come in contact with the skin in any stage of the operations. This can easily be done by wearing india-rubber gloves or finger-cots, and washing thoroughly the bichromate out of the prints before the development, as the warm solutions, no matter how diluted, will facilitate the absorption of the salt. But if by unforeseen accident the disease breaks out, it would be the greatest imprudence not to cease immediately to work by the bichromate processes until radically cured, for the salt in contact, with the sores (or the mucous) might penetrate into the circulation to such an extent that a true poisoning would follow. The disorder would then in some cases be so grave as to necessitate the amputation of the arms, and to endanger even the life of the patient.

RECENT ADVANCES IN THE APPLICATIONS AND SCIENCE OF PHOTOGRAPHY.*

CLASSED among the industries of Great Britain, it may be fairly presumed that photography has in recent years made some advance both in simplification of process, and in its applications to commercial purposes; and if we compare its present condition with that of ten years ago, the presumption is fully borne out. Yet if we take any particular year of the decade, it will be found impossible to allot to it any important forward step as regards the art-science—a sure sign that the progress made has been steady rather than rapid or in bounds. Ten years ago, for instance, our bookstalls were not adorned with periodicals whose *raison d'être* appears to be the publication of photographic prints of certain celebrities, nor did we find biographies and books of travels illustrated with photographs of persons and places, nor yet an artist's pen-and-ink sketch reproduced in *fac-simile* by the action of light on a metal relief block or engraved plate. To-day all of these applications of photography are common enough, and excite no surprise. The uninitiated, however, are little aware of the costly experiments and often unrequited labour which have been entailed in order to bring them to a successful issue. In scarcely any industry has capital been more unremunerative, or the public so little appreciative of merit.

Since the price of the weekly or bi-weekly papers, which are illustrated with, in some cases, really admirable portraits, is only a penny or twopence, it is not hard to understand that some cheap method of multiplying the photographs must have been discovered. Moreover, it must evidently be one which possesses marvellous delicacy, since the prints show all the delicate tints representing light and shade which rival the well-known silver productions. The process answering these requirements is the Woodburytype, so called from its clever inventor, and it will not be out of place to give a general outline of it. It may be said to be based on the production of a "squeeze" or mould in soft metal from a photographic print, in which the gradations of light and shade are represented by different thicknesses of gelatine. Into such a mould, which shows all the minutest differences in level of the original print, liquid and coloured gelatine is poured, and the excess is squeezed out by a flat plate being brought to bear on the paper, under which the mould and its contents are placed in a suitable press. The "shape" of jelly when set is removed with the adherent paper, and is allowed to dry, the metal mould being again available for a similar operation. Here, then, we have a means of producing prints by the thousand from photographic *etches*, or negatives, the cost of production being principally dependent upon the price of the coloured gelatine and of the labour.

There are other mechanical photographic printing processes before the public which are not used to such a large extent as the Woodburytype, being patronized more for commercial advertisements than for art purposes. To these may conveniently be given the generic name of "collotype," since the prints consist of surface impressions taken from a gelatine film

without the intervention of a metallic mould. We have seen how in Woodburytype a gelatine image in relief is necessary to form a stamp for the mould, but in these we have the image lying in a film of insoluble gelatine, and showing its presence by the difference in absorption of water by the light and shades. When such an image is produced in a film of gelatine and is moistened, it can retain greasy ink in exactly the inverse proportion to that in which it retains the water; and if lithographic ink be applied to it by means of a roller, a black picture, in all its gradations, is formed, capable of being transferred to paper by pressure in an ordinary printing-press. A certain amount of trained skill in applying the ink is required, and these processes are not, therefore, perfectly mechanical in practice, something being dependent on the judgment of the printer. They are, however, excellent as applied to photographs of machinery, trade articles, and landscapes, while for portraits they are rather uncertain. The carbon process, exemplified in such perfection by the Autotype Company, is too well known to need any description. It is sufficient to say that each print is procured by the action of light on a gelatine film impregnated with bichromate of potash, which renders the coloured gelatine more or less insoluble. When the soluble portions are washed away the print remains ready for transfer to paper. On the same principle it is that the initial print for the Woodburytype process is secured, though the basis of paper is replaced by a collodion film. Thus it appears that the advances made in printing processes are all due to the knowledge of the change effected on bichromates when in contact with colloidal substances, a knowledge which we owe to the researches of our countryman Mungo Ponton, though elaborated by Poitevin and other distinguished workers in the same field.

The execution of photographically engraved plates and relief blocks in metal has long been a desideratum, and more than twenty five years ago we read of attempts being made to render it practicable. With Niépce's original photographic process with bitumen the greatest measure of success has been obtained, as with it it is practicable to form an acid-resisting image on a metallic surface. This surface can then be etched to the required depth, the bitumen image protecting the necessary portions, and prints can be pulled from it in the ordinary manner. Other methods are based on the production of electrotypes from gelatine images, and meet with great favour in some quarters; for instance, the beautifully executed maps of the Austrian Government are believed to be produced in this manner. Every day, indeed, these photographic blocks and plates are coming more into use commercially; in America we find weekly and even daily journals largely illustrated by cuts photographically reproduced; and some of our own periodicals indulge in them to an extent which an adept can discover is by no means limited.

In the facilities offered for taking photographic negatives, also, we have had a remarkable advance through the introduction of what are technically called the "emulsion" processes, which for rapidity and delicacy of image rival the old wet plate, and for simplicity entirely distance it. A photographic emulsion consists of a highly sensitive silver compound held in suspension in collodion or gelatine. When in the former, a glass plate has merely to be covered with a film of the fluid and then allowed to dry in the dark, when it is ready to receive and retain an impression of the image optically formed in the camera. When in the latter, though the manipulations for preparing the plate are rather more prolonged, yet when finished we have a surface which is sufficiently sensitive to be impressed by objects illuminated by lamp or gas light. For the amateur the nitrate of silver bath and its inconveniences are banished from the laboratory; and the stained fingers and clothes arising from the ordinary mode of bringing out the image on the surface are avoided by employing the alkaline method of development discovered by Major Russell some years ago. The load that the landscape photographer has to carry in the field has also been diminished by applying this emulsion to long bands of impervious paper, by which plan material for the reception of one hundred impressions can be carried with less inconvenience than half a dozen glass plates. To Woodbury and Warnerke the credit of this invention is due, which would have been incomplete, and in no way superior (except as regards rapidity) to the old waxed paper processes, had not the latter shown us how the developed film could afterwards be transferred to glass for printing purposes. To the traveller unacquainted with the practical operations of photography this invention is doubly useful, as a band of this sensitive paper can be transmitted by

* *The Times*.

post, and the images impressed on it, perhaps thousands of miles away from home, can on arrival be converted into ordinary negative pictures, provided only that the duration of exposure to the lenticular image has been sufficient.

(To be continued.)

PHOTOGRAPHY ON WOOD.

BY PROFESSOR J. HUSNIK.*

RECENTLY I have been much engaged in attempts to obtain photographs on wood. The principal objects that I desired to secure were first, that the photographs themselves should be in an inverted position; secondly, that the wood should be acted on as little as possible by moisture and the different chemicals employed in the process.

My first attempts were made with white of egg and silver nitrate, but partly owing to its coming into contact with the caustic, partly in consequence of the many baths that it had to undergo, I found that the wood became soft and warped. This defect I endeavoured to get rid of by rubbing down the surface with pure water and chalk, and then coating it with caoutchouc; thus prepared the wood was dipped in white of egg, and submitted to the usual silver chloride process. The results obtained in this way were satisfactory, but the necessary labour and trouble were immense. In the ordinary silver chloride process on paper, where a complete photograph on paper is produced, when inverted negatives are not required, and where several pictures can be copied and manipulated at once, the work is trifling; but when in this case we take into consideration all the difficult operations, the troublesome drying of the wood after each copy, and further, the inversion of the negative, we should have to charge such a price for photographs of this kind that no one would care to pay it; it would be readier and cheaper to have the drawings made in the usual way.

I next turned my attention to producing pictures on wood by the bichromate process, using gelatine instead of albumen, and obtaining images of different colours by the addition of various metallic salts. Here, though the costly employment of gold was no longer necessary, and the operations were shorter, the price could not be much lower, so that I was compelled to find another and cheaper method.

The dusting-on process by means of the iron salts gave me a positive which, by aid of a collodion film, could be transferred to wood. In this case there was no tiresome manipulation of the wood necessary; but inverting the negative and washing the collodion film with ether were still troublesome operations.

At last I hit on the idea of taking collotype impressions on wood. Collotype plates were first prepared, and prints from them taken on pasted paper; these were laid, while still wet, on the wood, and then rolled up in a burnishing press. This method I found very satisfactory, for I had not to prepare the wood blocks, and of collotype plates I have a good store; only the negatives were obliged to be inverted.

I then tried to produce the collotype plate on a thin sheet of zinc, from which a direct impression could be taken on wood. This answered in every respect; moreover, the inversion of the negative was completely avoided, for an inverted positive was obtained on the wood-block. Fixing the gelatine film to the thin zinc sheet can be effected with certainty, but that, as well as the preparation of the collotype plate, requires skill and experience, as the sheet of zinc, which is as thin as paper, is never quite plane, and therefore cannot be dried in the same way as a plate of glass. (On a future occasion I intend to explain this method of preparing collotypes, in which I take Obernetter's experiences as a guide.) To obviate the last named difficulty I next adopted the method of exposing gelatinised paper alone under a negative, and when the chromium salt had been washed out, placing it on a plate of glass, and laying on the ink with a very small glue roller. With this I succeeded completely; I obtained beautiful pictures, perfect in the

half-tones, which could be at once laid on the wood-block, and be printed off at one impression. Gelatine paper can be easily prepared, and kept in stock, according to the process described in my book "*Das Gesamtgebiet des Lichtdrucks*," by placing sheets of paper in a perfectly horizontal position, and coating them with a dilute solution of gelatine, and they need only be sensitised at the moment of use with a one per cent. solution of chromate; by this means the above described method is rendered thoroughly simple and practical, as well as being certain in its results. The wood-block itself requires a very simple preparation; it must be rubbed down with whiting to which some adhesive substance has been added. This rubbing can be best effected by the ball of the hand. Gelatine paper can also be purchased from the dealers, and even my own photo-lithographic transfer paper will answer the purpose very well, provided that, before immersing it in the chromate solution, it be wiped over a few times with a damp sponge, and then rinsed well in clean water. This is done to remove any soluble matter from the surface. Afterwards the paper is dipped for some minutes in a one per cent. solution of chromate, then drained, and hung up to dry at an ordinary temperature. Sensitised in this way it remains good for the above named purpose for from three to five days.

WHY SITTERS MOVE—AND THE REMEDY.

BY H. J. RODGERS.*

"You didn't keep still—shall have to try again." Some photographers seem to have learned this intuitively! There never was a result without a cause; but, with many operators, "double lines," dimness of the whole figure or in sections, proceed from one and the same cause, and it is too convenient to charge sitters with nervousness. It the negative plate, from carelessness, don't happen to be placed down properly in the plate holder, and the result is an indistinctness (especially of the head), then of course the sitter is a "bad subject to keep still." It does not seem to be good policy to charge the sitter with nervousness, as it has a tendency to make matters worse. Some other excuse for making a "sitter over" would be better. Then, again, it would be well oftentimes to inquire whether the sitter, the floor, or the camera moves. Suppose during the exposure the impatient operator should, in a restless manner, step this way and that, resting his body on this foot, then on the other, wouldn't the camera move? And it is precisely the same effect in the negative as if the sitter moved. Suppose, again, during exposure the operator gazes rudely at a sanguine nervous person, that is inclined to modesty; or that if he stands by the camera in such a position that the sitter can bring his side face in the range of the point of vision. The sitter is in an uncomfortable spot generally—looking and winking at a mark. There is fear of moving, because of having been told not to move. There is a dread apprehension in the mind, and the feeling is not altogether home-like. The expression changes from sunshine to shadow—from timidity to fear—alternately, and the whole being seems encircled in a halo of the conjugal and mystical. Well, the sitter moves.

If the operator (when all ready to expose the plate) would just turn around with his back to the sitter (old-fashioned way) and then say, "Feel happy; you are all alone!" ninety-nine out of every one hundred would keep perfectly still previous treatment having been favourable. Many operators, become unconsciously brass-lined in a physiognomical point of view, and forget that there is such a thing as diffidence in an embarrassing place—such a beautiful and elegant trait of character as modesty. Another very common annoyance in moving is from a jar of the floor through various causes—the different kinds of industry which the building may contain—the action of heavy wind or vehicles passing by. There are, of course, many people who move from effects of ill-treatment received previous to sitting. The remedy of this great evil is a matter of much importance. Take, for in-

**Photographische Wochenblatt.*

**St. Louis Practical Photographer.*

stance, people of refined temperament and delicate constitution. It is quite an undertaking to prepare for a picture. Although this preparation is unnecessary, yet fastidiously inclined people have a fervent love for the beautiful, and cultivate and prepare for it. At any rate, a person, after getting tired and climbing up into third and fourth storey studios, don't seem to be a hardy subject enough to be treated in a rough and ill-becoming manner. How many reception-room attendants do we find who are formal and unapproachable; not educated (in fact, nothing to educate); inflated to a bursting capacity with coarse, shoddy-clipped city airs; colder than a Hump-Ke-Dunk cucumber, and more indifferent than the weather-cock on a farmer's barn is to the cackling hen. Why is it not just as easy to be a little more humane—a little more filled with human regard and sympathetic feelings?

From this chilling reception the patron is ushered (sometimes in a hurry) into the long-dreaded operating-room to take the second degree in the process of "tempering and hardening."

Here, sometimes, the operator is equally cross, fretful, and impatient as the reception-room attendant. He complains over the perplexing results of which he has been the sole cause. He continues to become irritable, and grows blind with nervousness, and is unfit to prepare his sitter for that mood that is required for an every-way successful result. If the operator is quiet and gentlemanly in manner—exhibits a desire to *gratify* every suggestion and whim—even, if he don't) if he would "shut off" this incessant talking—let every word be studied to please—make his sitter feel "perfectly at home," his "sit overs" would diminish in number, and his avocation would become one of pleasure. Then, again, these efforts (if efforts they are) will certainly be crowned with success—for he that conquers himself is far greater than he who conquers an army.

WHAT I KNOW ABOUT PHOTOGRAPHY.

BY E. H. TRAIN, OF MONTANA.*

ARRANGE your dark room so that it can be kept cool in summer and warm in winter, and be well ventilated (for health). Learn your light, and get control of it so that you can get your lights and shades to fall to suit you, taking care that the light on the eye is right, and do not get a "blind light" over the pupil. Buy none but the best chemicals of reliable dealers. Now take a gallon of distilled water (more if your bath dish will hold it, and it should not hold less); add nitrate of silver enough to make it thirty-five or forty grains to the ounce; when it is all dissolved, separate one-third from the rest, and saturate the two-thirds with iodide of silver; filter well, and pour back the other third; sun a day or two if you have time, or it will work without. Prepare your collodion after any good receipt.† Next put four ounces protosulphate of iron in a two-quart bottle, add sixty-four ounces water, cork tightly, and lay it on the table or floor, where you can give it a roll semi-occasionally, and it will be soon dissolved; let it settle, and filter off sixteen ounces, to which add one ounce acetic acid No. 8, and just enough alcohol to make it flow (which will be very little at first, and more as the bath accumulates alcohol from the plates dipped), and you a reliable developer. Now try a plate, and see if it works clear. If there is any fog, add nitric acid C. P., a little at a time, to your bath until it works clear.

The above is probably not the best formula in the world, but it is a thoroughly reliable one. Now your chemicals are all right, place your sitter so that his pose looks easy and graceful on the ground glass (pay no attention to anything else); slide your head-rest up until it just steadies his head without changing its position; talk him into a good humour with himself and the world; and "shoot your gun off," and if you do not get a good picture it is

* Philadelphia Photographer.

† In this country it is better to buy a good commercial sample, of which there are many.—ED. P.N. ¶

your own fault; and if you do, you can do the same thing every time, as long as the conditions remain the same.

The next thing is to know where to look for trouble when trouble comes. I see that some writers (who, by the way, are fine artists, and have had much experience) say they always look for it in their collodion. With me, on the contrary, if the trouble is not in the temperature of the rooms or chemicals, in ninety-nine cases in a hundred I find it in the bath. Heat causes various and sundry troubles, and cold some, although it is not so much to be feared. In hot weather, keep your bath, developer, and plate-holder cool. Immerse your plates with a very slow but even motion, and let as little time as may be elapse between the sensitizing and developing of your plates, and you will have little trouble from this source. But, to return, the change in collodion is very slow, and always in the same direction, and any sample that will work clear once ought to always, or at least for a long time. Of course it will lose sensitiveness with age, and will grow thick in the bottle you pour from, from evaporation, but that is about all; while the change in the bath, particularly if it is a small one, may be rapid from the foreign matter introduced with the plates. I know that a change of collodion will sometimes remove a difficulty for the time, when, if the bath was all right, both samples would work. To illustrate, I once left my gallery in Montana (it is a long way from any place) in charge of a friend for some time, and when I returned he complained that none of the cotton that I left him would make collodion that would work, and he had to send to Philadelphia for some, and showed me several bottles that he had made at different times and condemned. I renovated one of his baths, and produced excellent work with every sample of his condemned collodion. But, from all this, I do not want you to infer that I would advise you to be always doctoring your bath; on the contrary, having gotten it in good working order, I recommend that you let it severely alone; put into it absolutely nothing but the cleanest of plates, and these only when necessary. Do not call in every paper by which to try your "kimicals" on; so long as it works satisfactorily, do not change its quantity or quality. If a scum gathers on it, skim with blotting or filtering paper, and filter it only when necessary, and it should work for a long time. When, however, you do get into difficulty, be sure first that it is not caused by the temperature of your rooms, or some similar cause, and that your collodion and developer are the same that have been giving good results; and then, if a little more acid in your bath will not set you right, I know no remedy but to renovate your bath by neutralizing and boiling, and that is a remedy that has never failed me for the last twelve years.

To be sure "that none go away dissatisfied," you should always have two or more baths in good working order, for it does not improve your reputation as an artist to tell people that your bath is not working well to-day, and they will have to come again. Usually, they will come no more for ever.

To albuminize plates, soak them a few hours in dilute nitric acid, wash thoroughly, rinse with dish water, and flow with albumen. While wet, flow them with about one-fourth ounce albumen to four ounces distilled water. Letting your plates dry after they come out of the acid will make the albumen refuse to flow.

Now, we can make good negatives; but about retouching, "aye, there's the rub!" That takes long and careful practice to do it well; but a few hints may not be amiss here. Round up and smooth your negative nicely, being very careful always to preserve and beautify the likeness. Soften and blend, but do not obliterate your shades. Look to the end of the nose; it usually wants some retouching, and is often overlooked; and to the eye; but here you must be very careful. In all your retouching, strive to make it so fine that your prints do not show it.

PHOTOGRAPHY DURING THE PAST YEAR.

FOR many years past in photography the seasons have come and gone and seen but little change. Steady and gradual improvement there has been, but no revolution in methods or processes. The last important change in practice, which began to be discussed about twenty years ago, was the supercession of pyrogallic acid development by iron. Much angry discussion as to the advantages of bromides in collodion and iron development preceded the general acceptance of the new system, which issued in greatly reduced exposure and improved quality of negatives. The old method was, however, defended with much tenacity, and was eventually superseded only by the stern logic of facts.

The next revolution in the mode of producing negatives will probably be more radical than the last; for, unless we mistake the signs of the times, the change will be from wet plates to dry plates, from the use of the nitrate bath for sensitizing plates to the use of emulsions. And the change will bring with it not only many elements of convenience, but increased rapidity of exposure.

The advance in general recognition gained by emulsion processes during the year is almost startling, and may be regarded as amounting to a revolution. Emulsion processes generally have during the year improved considerably, gelatine emulsion, especially, having made an extraordinary stride. Mr. Kennett, the introducer of gelatine emulsions, has steadily, during the few years which have elapsed since their introduction, worked at the processes, and maintained their superior sensitiveness, but until the present year he has had to bear the burden almost entirely alone, and of the people there were none with him. But during the past twelve months a silent revolution has taken place. Mr. Wratten has introduced a singularly ingenious method of washing gelatine emulsion, and not only so, he has produced plates of marvellous rapidity. Mr. C. Bennett, until a few months ago a comparatively unknown amateur, has astonished the photographic world by producing gelatine plates of such rapidity that he has produced upon them drawing-room interiors lighted with ordinary gas lamps; and Mr. Swan has produced commercial dry plates with gelatine of such rapidity and certainty that in the hands of many they supersede wet collodion for portraiture in the studio! Mr. Wm. Brooks on similar plates has produced interiors of dark underground caverns lighted only with paraffin lamps! The dry record of a few definite facts states with more eloquence than any carefully-prepared and glowing periods the nature and extent of the revolution which is in progress, and for which many photographers are still unprepared.

Thus the least pretentious and most unobtrusive has

been the most important work of the year. But other progress has not been wanting. Carbo printing, which, during the last few years, has been extending more or less tentatively, has, during the year just past, largely made good its ground. The doubts thrown upon its permanency have aroused attention to the subject, and the system has come out of the scrutiny with renewed vigour, and obtained general confidence. The fears expressed at the beginning of the year by Dr. Vau Mouckhoven, an early adherent of carbon, that the received method was not so trustworthy as was believed, and that there were elements of instability in carbon prints as usually produced, naturally occasioned much consternation. But the investigation which the suggestion promoted issued in renewed conviction that pigment printing, carefully conducted and with honest pigments, produced absolutely stable prints; and that the causes which led to the note of alarm were individual or local. Another alarm of a similar character arose from the experiments of another gentleman whose name was associated with early effort in securing permanent printing—Mr. Tunny, who, jealous of any doubt where permanent photographic printing was concerned, was induced to make experiments which issued in undoubted change in the prints under examination. The white portions of the prints became yellow under the action of light, as silver prints had changed under atmospheric influences. The announcement of this fact led again to renewed research, and again the obnoxious results were found to be traceable to accidental conditions: a sample of transfer paper to which the completed prints had been transferred was found to change under the action of light, losing its purity, and becoming yellow in tint. As a general issue, pigment printing stands firmer in public estimation than ever. Increased experience has been acquired as to the conditions of successful working, and a definite extension of this form of permanent printing is the result.

An important stride in permanent printing has been made by Mr. Willis, by the improvement in his platinum printing process. This ingenious method, when produced a few years ago, was at that time somewhat coldly received when it was known that both silver and hyposulphite were elements in conducting the process. It was alleged that they were only incidentally used, and were in nowise major elements in the process; but photographers—even those who adhere to the old method of printing—were indisposed to make a change unless their arch-enemy, hyposulphite of soda, were altogether eliminated from the new operations they were invited to adventure with. Mr. Willis has made a simple improvement in his process whereby the use of silver and hypo are both banished from his operations; and he now produces, simply and easily, images in pure metallic platinum of an intense black tone, of the stability of which no reasonable doubt can be entertained. Other noble metals, gold and palladium, and iridium, are said to be equally valuable for his purpose, and thus variety of tone may be obtained.

In ordinary photographic operations little change has been made. In the profession of portraiture, "trade" has been dull; and novelties have not been rife. The use of artificial light in portraiture has again excited considerable attention. The electric light, and the use of pyrotechnic compounds, governed by diffusive and reflecting agencies, have presented considerable promise.

Photography in its scientific phases has made more advancement than it had for some time previously. Captain Abney, an investigator of much ability, great perseverance, and rare conscientiousness, has fortunately devoted himself to this aspect of the art science.

At the great exhibition held in Paris, English photography, although but meagrely represented, took high honours, four gold medals having been distributed to exhibitors, and one decoration of the Legion of Honour, Mr. Dallmeyer having been the worthy recipient of the

honour which Frenchmen covet more than any other prize in the world. The Photographic Society's Exhibition in London was a success, although scarcely up to its usual mark.

Photographic societies maintain a healthy existence generally, without making much progress; but all those in existence are successful, and apparently highly valued by their members. There is room, however, for more of them.

FRENCH CORRESPONDENCE.

ENLARGEMENT BY THE GELATINO-BROMIDE PROCESS—A NEW PYROXYLINE FOR EMULSIONS.

Enlargement by the Gelatino-Bromide Process.—The process by means of the gelatino-bromide appears to be decidedly taking root among us. For some months it has now been much studied, and indefatigable investigators like M. Durand of St. Etienne, and M. Boivin, have succeeded in introducing not only great improvements, but also considerable simplifications, and in largely developing its applications. Very recently I have again received a letter from M. Durand containing some most interesting details of the means adopted by one of his friends, M. Blachon, an amateur, for employing this process in enlarging. His method of working is very simple. He commences by taking a negative in the camera on a plate prepared with gelatino-bromide, which he then develops, fixes, and washes as in the usual way. This plate he then lays in a dish of water to which 7 or 8 c.c. of ammonia have been added for every 100 c.c. of water. After remaining in this bath for a couple of hours the edges of the film begin to shrivel, and bladders are formed on its surface; the film then separates entirely from the plates and floats on the top of the water. It is then seen that the gelatine under the influence of the ammonia has distended itself, and the picture is therefore found to be considerably enlarged. This effect is analogous to that which is obtained by the instrument employed by lithographers for enlarging their drawings. In that case the drawing to be enlarged is transferred to an india-rubber disc, and when this is uniformly extended in all directions, the dimensions of the drawing are increased to the required degree. In the case that we are considering, when the pellicle, on which is impressed the photographic image, is detached from its support as above described, a glass plate of the necessary size is slipped beneath it, and as soon as the film adheres to it the plate is withdrawn from the water, and then placed to dry. By this means we obtain a very delicate picture, enlarged to about four times its former size, which can be intensified to any required extent. The thicker the film of gelatine, the more the print can be enlarged; at the same time an enlargement of four times in superficial area can be obtained with a film no thicker than those which are generally employed in taking landscape negatives. Detaching the pellicle from the plate on which it was originally formed can be facilitated by using a paper-knife or some similar instrument of bone or ivory. If, after being detached, the picture is not sufficiently enlarged, it is advisable to raise the temperature of the bath in which it has been immersed by adding in succession small quantities of water, each of which is hotter than the one preceding. In describing this process, due to the researches of his friend M. Blachon, M. Durand draws the two following conclusions:—(1). It is very important in the preparation of gelatino-bromide plates, as in the sensitising of carbon tissue, to ensure complete and rapid desiccation, in order that the adherence of the gelatine to its support may be as perfect as possible. (2). It is also necessary to avoid submitting the gelatine films for too long a time to the action of alkaline solutions, or to those of a high temperature. By paying attention to these two rules, and by employing an alcoholic bath for sensitising, as pointed out by M. Boivin, M. Durand asserts that he has never had occasion to observe the formation of reticulation or bubbles in his carbon prints.

A New Pyroxyline for Emulsions.—Apropos of the Russian gun-cotton recently brought into notice in England by M.

Leon Warnerke, M. Boivin, in a letter I have lately received from him, makes some remarks on a pyroxyline which he has used for some time with great advantage in the preparation of his emulsions. The method of preparing this substance was communicated to him by an army doctor, Dr. Touraine; it has been in use in military hospitals since the year 1835 for dressing wounds. The cotton is deprived of all gummy or resinous particles by means of alkalies, and this treatment makes it easily penetrable by acids, either at a high or a low temperature; it is thus admirably adapted for the preparation of all kinds of collodion. Up to the present time this gun-cotton is known under the name of *coton hydrophile*.

ERNEST LACAN.

INSURANCE RATES ON EXPORTED COLLODION.

BY NELSON K. CHERRILL.

I HAVE just received by the last English mail an invoice of charges made on the shipment to me of two cases of collodion, to which I think it would be well to draw the attention of those of your readers who are concerned in such matters.

The point to which I wish to draw attention is the absurdly high rate at which only insurance can be effected on such goods as collodion. I am charged at the rate of fifteen guineas per cent., and my shipping agent sends me a memorandum to the effect that that is "the very lowest" at which such an insurance can be effected, and that many are paying as high as twenty and thirty per cent. for the same risks. Now why should such enormous charges be necessary? There is no inherent danger in collodion, that it should render such an almost prohibitive insurance rate in any degree necessary. The charge finds its origin, I believe, in the superstitious ignorance of seafaring men, who regard chemicals of any kind as a species of devilry, and are glad of the smallest pretext for getting them off the ship. By one of those ingenious regulations by which merchant shipping is hampered, it is ruled that collodion, even though properly packed in tin-lined cases, may not be stowed in the hold of the ship, but must be loaded on deck, and, as I say, a deck-loaded case of collodion seems to be an object of terror to the sailor; he has a sort of professional spite against it, and at the smallest provocation, overboard it goes. I had an illustration of this only a few months ago, when a ship coming out here had on deck a case of twelve dozen of collodion for use. She shipped a sea which broke loose a hen-coop, and did some other trifling damage; but the occasion was only too tempting to the officer of the watch, who instantly ordered my collodion overboard for the benefit of Neptune's special artist. Again, to show that this summary treatment is quite the rage with the sailor mind, I might mention that I have just heard of another case quite as much to the point. Some relatives of mine, just landed here, came in a ship with some Government emigrants on board; on account of the emigrants, a case of collodion was refused freight. The matter was spoken of on the voyage out, and one day a storm sprung up, when one of the officers said to my relative, "It's a good thing your friend's chemicals were not here, because the first thing I should have done would have been to throw them overboard."

Under these circumstances, I think some steps might be taken to relieve Colonial importers of photographic materials from these additional risks, and consequently additional expense. It surely must be that the nature of collodion is not understood in the inner circle of those who make the regulations for shipping such goods. What more danger there is in a case of collodion packed in tin, than in a case of brandy packed in straw, it would puzzle many of these wise heads to say indeed; so far as danger to the ship goes, there is far more danger attending the shipment of wines and spirits than in almost any other class of goods, though the danger arises indirectly from the depravity of human nature, inasmuch as the sailors are almost sure to enter the hold and broach cargo, whereby the chances of fire are enormously increased. Indeed, I am told on good authority

that one-half the fires at sea are caused by this very thing. But this is a digression.

Very many of your readers are interested in this matter, and I cannot but think that if some steps were taken by export agents in London, aided by an expression of opinion from yourself and some of your more influential contributors, that perhaps the present regulations might be so modified as to enable collodion to be packed in the same way as alcohol, varnish, turpentine, and other equally combustible and not less dangerous compounds. If this were done it would make collodion at least fifteen per cent. cheaper in the Colonies, and what is, perhaps, on the whole quite as important, it would present an enormous annual waste of this article, as I cannot believe that Neptune's best artists can do any good with what the sailors so freely give him, as the salt in the sea would spoil his baths; and besides, his studio is very badly lighted.

THE NITRATE BATH.

MUCH used, and always abused nitrate bath. From the earliest days of photography till the present, the nitrate of silver bath for negatives has come in for its full share of blame for causing failures that it was entirely innocent of, and it will always be so until the day comes (if it ever will) when photographers will learn themselves the nature of that bath; what it is composed of, what it is required to do, and how it should be kept.

We might compare the nitrate bath to the human system. Let nothing go into it that will derange it; let it be governed by chemical laws, the same as the system is by natural laws; disregard the above, and they both will get out of order, and want doctoring. Now, we could fill a whole number of this journal on the nitrate bath alone, and not exhaust the subject, so we will confine our remarks to essential points, bearing in mind that everything that comes in contact with the bath must be pure and clean.

There is no doubt but that fused silver will make the most rapid working bath (if pure). Distilled (or filtered ice) water is also essential; pure iodides and bromides, and especially pure alcohol and ether, and some reliable brand of cotton for your collodion. Let any or all of these articles be impure, and it will disorder your nitrate bath. In cleaning your glass by the polishing method, or albumenizing it, especially if you use so many decoctions to preserve your albumen pure, this makes the bath impure. We have never found anything as good as pure albumen from fresh eggs cut up with fine glass in a bottle.

Albumen	1 ounce
Ice or distilled water	15 ounces

Then filter before using it. Leaving your bath uncovered will make it impure; leaving a plate in too long, or coating dirty plates, will produce the same effect; using different brands of collodion in the same bath will make it impure, the same as a change of food will often disorder the system; in fact, there are many things that tend to disorder the nitrate bath that are hardly thought of in our daily manipulation, such as handling your glass without thoroughly washing your hands after developing or fixing. This is one of the greatest sources of introducing impurities into the bath. Introducing carbonate of soda, ammonia, cyanide, permanganate of potash, acids, all tend to get the bath out of order. Any of those introduced into the bath may improve it for the time being, but it soon gets out of order again, and wants doctoring. We contend that a bath made pure in the commencement, and great care taken in using it, will last for years. Keep out all impurities when weak; add pure silver and water, and if your dipper does not reach within one or two inches of the bottom bath, it will not want filtering once a year. We know many galleries that work large baths that never think of filtering them from one year to another. One great cause of foul and impure baths is

the smallness of them, many not holding more than a pint, quart, or half-gallon of solution. So many ask why the large galleries make such fine uniform work. The secret is that they use large baths, holding from one to four gallons of silver solution, and never allow them to get out of order, by being careful in their manipulation. That is the principal secret of fine clear negatives in continually doctoring your nitrate bath.

Silver	40 grains
Water	1 ounce

is a good standard to make a new bath by. It will work some seasons, well down to thirty-five or thirty grains, and up to fifty in very cold weather, if you have not your dark room warmed up. There are several ways of sensitizing a bath, but we prefer to coat the largest plate we can get into the bath, and let it remain in overnight, and if it heats off all the iodide that is in the collodion film, dip another. The bath will eat off only as much as it needs; it is generally considered the best way to make the bath slightly acid. We have always found it to work best at that stage. After your bath is mixed, acidified, and iodized, filter it through clean filtering cotton, or pure filtering paper. In all well-regulated galleries, two negative baths should be kept constantly in use, and in good order, especially where you have not the convenience of a very large bath; even then we would advise two baths; it pays in the end. If a bath shows signs of failing, which many will by not following the within instructions carefully, we advise the following:—Pour your solution into a large bottle (not more solution than to half fill it), then add pure water until it turns milky or creamy; shake it up well; let it stand in the sun, or (indoors it takes longer) till it settles clean; then filter it, being careful not to pour the sediment into the filter; next boil your solution down to about the original bulk it was, or to the quantity you may want; test it, and if not forty grains strong, add fresh silver to make it so, but if over, add pure water to reduce it; filter then, and it is ready for use. This bath does not want sensitizing, as there is generally enough of the iodizing solution left in the bath to make it work right off. This doctored bath generally works quicker at first start than a new bath. Test it, and see if it is alkaline or acid, and doctor accordingly; if neutral, add a few drops of diluted nitric acid. It is always best to introduce acid into the bath by diluting it first with a small quantity of water.

Seldom a nitrate bath wants boiling down to the fusing point, except ferrotype baths. If the above course is adopted, you will have but little trouble with your negative bath. It is a good plan to keep on hand some pure bath solution mixed in an extra bottle about sixty grains strong. You have no idea what life it gives to a weak negative bath to add fresh silver (unless you have tried it). When your solution in your bath gets low, you should never let your dipper touch the bottom of your bath unless you want imperfections such as comets and pinholes; keep the lid of your bath at an angle, so that dust and impurities will not get in, but ether and alcohol will get out. After your negative glass is well coated and set, dip it carefully in your bath, slow, and never stop till it is thoroughly immersed; when coated, which takes two or three minutes, according to the temperature of the solution, take it out quick and let it drip a minute or so on a couple of wooden pegs or a little dark closet that some have in their dark room for that purpose, and you have no idea what an amount of silver you will save in a year by catching the drippings.—*Practical Photographer.*

Correspondence.

THE FERRIC OXALATE PHOTOMETER.

SIR,—Your correspondent "Historiens" (I presume he is not the able writer to the *Times* who uses the same pseu-

donym) has in the last issue doubted the accuracy of a statement I made to the Photographic Society at its last meeting. It was quite probable that, in a discussion which arose on the spur of the moment, and trusting to memory, I might have made a misstatement, but I find that I am substantially correct. In an article in his Scientific Memoirs, Draper gives a detailed description of the ferric oxalate photometer in an appendix to that of his chlor-hydrogen photometer. The amount of chemical action of radiation effected on ferric oxalate was found by noting the amount of gold which the ferrous oxalate precipitated from a solution in a given time, or by measuring the carbonic anhydride given off. The chlor-hydrogen photometer was described in 1843, and presumably the ferric oxalate photometer was introduced somewhat later, but during the period in which Draper was paying attention to actinometry.

The remark that Draper makes in the same volume is corroborative of this idea. He says: "It may be remarked that the (ferric) oxalate is an excellent photographic substance. . . . I have in my possession photographs made by both these methods (i.e., developed with silver nitrate and tri-gold chloride) more than thirty years ago, which have undergone apparently no deterioration." "Historicus" will therefore see that at least in 1848 Draper was aware of the properties of ferric oxalate. Turning to page 173 of the second edition of Hunt's Researches on Light (1854) a description of the use of ferric oxalate is also given. In the Transactions of the Royal Society, Herschel also mentions that it can be employed for photographic purposes. One can scarcely suppose that Dr. Phipson in 1860 was in ignorance of the uses to which ferric oxalate had been put, though I have not his papers by me to see if this were the case.—Yours faithfully,
W. DE W. ABNEY.

THE LUXOGRAPH TESTIMONIALS.

SIR,—I note the correspondence which has been addressed to the photographic press by Signor Lombardi and Mr. Robert Faulkner. As my name has been incidentally mentioned therein, I feel compelled to trouble you with a few words of explanation.

I was present, in company with the above-named gentlemen, at a demonstration of the new Luxograph light, at Messrs. Alder and Clark's, and was so gratified with the results I witnessed, that I at once ordered an apparatus. Signor Lombardi's assertion that Mr. Robert Faulkner expressed his admiration of the new light—and that in no unmistakable terms either—is perfectly truthful; and I am somewhat surprised that the latter gentleman should now disavow that which I plainly heard, in common with Signor Lombardi.—Yours very truly,
EDWARD GREGSON.

Talbot Road, Blackpool, December 23rd, 1878.

SIR,—Permit me to state the facts relating to the luxograph testimonial—so distorted and exaggerated by Signor Lombardi in his letter published in your issue last week. Accompanied by my friend and operator, Mr. Ross, I witnessed a demonstration of the luxograph light. Pleased and amused, I yet declined to give Messrs. Alder and Clarke a testimonial as to the value of the light, or to purchase the apparatus until it was improved. Two days afterwards, talking over the affair with Mr. Ross, I thought I saw a means to fitting up the luxograph apparatus in an improved manner; and, at my request, Mr. Ross called on Messrs. Alder and Clarke to inform them of my plan, and to request them to supply a portion of the apparatus, for which I was willing to pay £15 15s.—a very liberal price for what I wanted. He was also to promise a good—not a "splendid"—testimonial as soon as I had tried the light and personally proved its value; also to supply them with copies of the pictures produced by the aid of the light. This offer was declined with the very significant remark—"As to Mr. Faulkner's testimonial, we can get that," the meaning of which became evident the following Friday. When the

luxograph testimonial written by Signor Lombardi was published, I then saw, to my surprise and annoyance, that my name had been put forward without my knowledge, as endorsing Signor Lombardi's enthusiastic and eulogistic opinion of the luxograph.

In consequence of a letter written to Messrs. Alder and Clarke, one of these gentlemen called on me. I requested him to withdraw my name from the advertisement, and to state that it had been added without my knowledge or approval. This he declined to do for the following reasons:—That he considered Signor Lombardi was my friend, and therefore must have known my sentiments on the subject, and that I had promised to give them a testimonial (when confronted with Mr. Ross he was compelled to admit that this was to have been given conditionally). I explained to him that if the practice of using a man's name without his consent were tolerated, there would be an end to all candid expression of opinion, and a system of mistrust would be engendered.

So far from Signor Lombardi being a friend of mine, I had only met him four times, and I knew nothing whatever of him except what he had told me of his ideas and mode of conducting his business; and, judging him from his own words, I should have a very strong objection to having my name associated with him in any affair whatever. The publication of my name, for the purpose of puffing the luxograph, was a piece of gross impertinence on his part, and of sharp practice on the part of Messrs. Alder and Clarke.

During the demonstration I heard Signor Lombardi ask to be taken into partnership, and from the fact that the offices of the Luxograph Apparatus Company are now at his studio it is only reasonable to conclude that an arrangement has been entered into between Messrs. Alder and Clarke and Signor Lombardi; hence his enthusiastic advocacy of the luxograph scheme, and his abuse of me is a mere vehicle for that purpose.

I regret exceedingly to have occupied so much of your space.—I am, yours, &c.,
ROBERT FAULKNER.

21, Baker Street, W., December 30, 1878.

THE PRIZE INSTANTANEOUS PICTURES.

SIR,—I cannot undertake to follow Mr. Jennings into his attempts at excuse. My knowledge of the matter is limited to my banding my friend's order to a trading firm, and that the order was not correctly executed. In my opinion, the Photographic Society should take notice of this improper dealing with prize pictures.

Mr. Jennings should have had the courtesy to apologize for his error, and the honesty to offer to exchange the wrong prints for right ones. H. STUART WORTLEY.

December 23rd, 1878.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held at the Memorial Hall, Albert Square, on the evening of December 12th instant; Mr. CHARLES ADIN, President, in the chair.

The minutes of the last meeting were read and passed. Mr. John E. Macdonald, of Cheetham, was duly elected a member of the Society.

The PRESIDENT read an address elaborating upon the subject of negatives and artistic photography, prefacing the same by some remarks in reference to the altered positions of officers in the Society, and in a very flattering manner spoke of the long friendship and esteem he had always entertained for the new Secretary, Mr. W. J. Chadwick, and hoped that their unanimous working would be felt and appreciated by the Society.

Mr. JOHN HOLDING said (as he also belonged to that body of artists whose pictures were produced by the aid of the pencil and brush) he felt bound to disagree in some measure with a few points in Mr. Adin's communication, and said the opinion *artists* entertained of photographers was, that they were mere "mechanical operators," and often, too stupid to listen to the advice of a

"artist like himself." Even on the occasion of the last excursion of the Society, he tried to persuade some of the members to take their pictures from a point of view which he thought superior to that which they had chosen, but they would not; they were "too clever," and would go on in their own stupid way in spite of his advice; and although many of their photographs were fair copies of the subjects they were to represent, they wanted "his eye" and "his ideas" to make pictures, and he could not agree with Mr. Adin that art was to be classed with rules. "Art was a natural gift, and could not be learned by rules."

Mr. ADIN said he thought many artists would do well to take a few lessons which photography could easily teach in the study of nature.

The SECRETARY then read a short communication from Mr. M. Noton on Mr. W. J. Chadwick's duplex gas lamp, which, it will be remembered, was before the members at the last meeting.

Mr. ROBERT KNOTT, who was unable to attend, sent two silver prints from carte-de-visite negatives which he had printed by the electric light, one printed at twelve inches distant from the light in fifteen minutes, and the other at twenty-four inches distant in thirty minutes. The latter, equal to half the exposure of the first, was by far the best and fully-exposed.

Mr. HARRISON GAITSIDE also exhibited a print by the electric light exposed under similar conditions.

Mr. GEORGE GREGORY then exhibited a series of excellent portraits, some of which had very pretty effects introduced; he exhibited the negative from which the prints were taken. He called attention to the method he had adopted, and although he claimed no credit to the originality of the "dodge," he thought it might be new to some and interesting to others. At the back the negatives were gummed, in some instances as many as three or four layers of thin tissue paper, portions of which were torn away in places where force in the picture was desired, and for introducing high lights, &c. He had found the tissue paper an excellent medium for "touching" upon. He (Mr. Gregory) also exhibited a landscape monochrome in oil, which was the subject of some little discussion.

The SECRETARY (Mr. W. J. Chadwick) said, at the request of several of the members, he had written to Mr. L. Warnerke, but as that gentleman was at present in Russia Mr. Payne Jennings had kindly sent two 12 by 10 transparencies printed on Warnerke's tissue. These were carried round and examined by the whole of the members with deep interest and admiration. Mr. W. J. Chadwick briefly explained the development and manipulation of these tissues. Many of the members were so interested to give the process a fair trial.

Mr. W. J. CHADWICK then exhibited in action the original oxy-calcium lamp invented by Canon Beechey thirty years ago for illuminating two or three optical systems of a magic lantern at one time by one light, consisting of a fountain oil lamp with circular wick, in which olive is burned with a gentle stream of oxygen gas passed through the centre of the flame. A small ball of lime is suspended over the flame, the lower portion of which, being rendered wholly incandescent, produces a light of great brilliance.

Mr. W. WATTS introduced a very novel and convenient little electric battery of great power for use with the sciopticon, and constructed to fit into the hollow space in the front portion of the base of that instrument; for displaying many beautiful electrical phenomena on the screen, such as the decomposition of water, &c., it was highly appreciated. He also exhibited some other apparatus in connection with electricity and lantern appliances, but as the evening was now far advanced, promised to enter more fully into the details on a future occasion.

The SECRETARY then called attention to three magic lanterns of the oil-burning family sent for inspection and trial by their respective makers. These were carried into the lantern room and lighted, but owing to the late hour of the evening many of the members wished to leave (having to go by train, &c.); the trial was, therefore, postponed for Saturday, December 14th, and twelve gentlemen were nominated to attend and act as judges. However, a short time sufficed to satisfy those present that one of French manufacture, although burning two two-and-half inch wicks, was inferior to the other two, viz., a Newton's lantern fitted with a *triple wick refulgent lamp*, and an improved sciopticon. This latter instrument had a recently introduced addition by which the picture could, by means of a movable stage and rack-and-pinion, be moved from the condenser, thus permitting it to be placed in the more concentrated portion of the converging rays, so that the whole (or nearly so) of the light was allowed to pass through the aperture of the slide.

On Saturday evening (the appointed time for trial) the President and those gentlemen most interested in the lantern gave judgment unanimously in favour of the sciopticon for intensity of illumination, whiteness of light, and better definition. The trial was conducted in the following manner:—The triple wick refulgent lantern and the improved sciopticon were placed on an elevated platform, and as the objectives of the two lanterns were not quite of equal foci, the lanterns were arranged at such distances that each projected a disc of eight feet diameter with pictures having the same size aperture ($2\frac{1}{4}$ inches); three slides were procured from Mr. Frank N. Good's negative of the lattice windows of Carlo printed in carbon and of equal density and colour, and so near alike that experienced photographers were unable to distinguish any difference. The judges, after seeing the lights in each lantern burning satisfactorily, took their seats beneath the lantern platform, so that they were unable to tell by which lantern the picture on the screen was shown, and as each was exhibited alternately, they gave judgment, and in every case decided in favour of the sciopticon. Next the two pictures were partly covered with a piece of opaque card, so that from each separately only one-half of the picture was shown (the same side of the slide in each case); but when the two lanterns were allowed to project their sinicircular pictures upon the screen at the same time, a complete disc was formed. The sciopticon half was again pronounced the brightest and best definition. The pictures were changed about and reversed with the same results.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

A MEETING was held October 1st, the President, H. J. NEWTON, in the chair.

The minutes of the last meeting were read by the Secretary, and on motion, approved.

After some routine proceedings,

The SECRETARY: Mr. Duchochois has handed in a paper which he requested me to read, and which he will explain, if necessary. (see page 2).

Mr. ROCHE: I have used bichromate of potassium in all manner of shapes, and it is a very dangerous thing. I am very careful to wear rubber finger-cots, and afterwards to thoroughly wash my hands not only in cold but in warm water.

Mr. HOGAN: I am surprised to hear that the gentleman has been suffering from the effects of bichromate of potassium. I have used it every morning for four years, and never have felt the slightest injurious effects; neither have my men. We don't take any especial care in using it.

Mr. LAMBERT: It may be more injurious to some constitutions than to others. I think the fault must be in the constitutional weakness of the person, and not in the process itself. The process is quite harmless, if care is taken in working it. Cyanide of potassium is an active poison, and really very poisonous if it touches the mucous membranes, more so than the bichromate of potash.

Mr. DUCHOCHOIS: I am surprised to hear Mr. Lambert say that the bichromate of potassium is quite harmless. Anybody knowing its properties will tell you that it is one of the most dreadful poisons used. Cyanide of potassium is a poison, it is true; but it will not go into the circulation as readily as bichromate of potash. We avoid a danger if we have any warning of it; but we have not had of this poison. Those who sell the carbon process do not even by a sign or word, spoken or printed, tell us of the danger of using it.

Dr. HIGGINS: Does Mr. Duchochois know personally of any other case similar to his own?

Mr. DUCHOCHOIS: Yes; the Spencers, two young men working in Philadelphia. Mr. Howard has been affected by it, and a lady in a well-known New York gallery. In Europe it is so well known that operatives refuse to work with it.

Mr. LAMBERT: If people mix it or take it from the bottle with their bare hands, or put it in the dish and stir it with their naked fingers, the poisonous effect cannot be wondered at.

Mr. MASON: There seems to be a misunderstanding in regard to this matter. I understand that Mr. Duchochois does not say anything against the bichromate process, but claims that there should be in the printed instructions sent out by the lessees of the bichromate process, or given to the workmen using it, something cautioning them against the improper handling of the solution; he does not condemn the process.

Mr. LAMBERT: Every bottle is labelled poison under the U. S. laws.

The PRESIDENT: Many things that are poisons are not poisons by absorption, as this is found to be.

Mr. DUCHOCHOIS: I will caution everybody that uses bichloro-mate of potash not to let it come in contact with any part of the body. It was the duty of the sellers to have told us this at the beginning.

Mr. LAMBERT quite approved Mr. Duchochois' remarks.

The PRESIDENT: I think it is the general understanding that explicit directions should be given that such articles should be used with care.

Mr. ROCHE exhibited some fine prints done by a process which he had devised by using ordinary printers' ink and a very simple press.

Mr. COOPER exhibited a large series of very beautiful carbon prints by a new process which he did not explain to the Society.* The experiment made by Dr. Higgins was as follows: A clean plate was flooded with bromo-iodized emulsion (formula not given), put in a printing-frame in contact with a negative, and exposed one second to an ordinary gas flame. Upon removal from the frame, a fully exposed and developed picture was seen.

Mr. NEWTON: After this very interesting experiment of the Doctor's, I have some things to show myself. Prior to doing so, however, I would like to say a word in reference to one particular paragraph of the Doctor's paper. It would appear by that as if I were indebted to the Doctor for my accelerator, the formula of which was read in the minutes of the evening. It is not the case.

Dr. HIGGINS: May I be allowed to state that I would not have it inferred so in the least?

Mr. NEWTON: I had tried alkali on plates before exposure long before I was acquainted with the Doctor or ever saw him. But the point in my accelerator and the experiments I went through with were to get the minimum amount of bromide that could be used; in that way I got the greatest degree of sensitiveness with the alkali upon the plate before exposure. Now I have some instantaneous negatives on emulsion dry plates. In the first place, the question has been frequently raised in reference to the keeping qualities of emulsion, and in the minutes of the last meeting, you will observe, some was spoken of which was over two years' old (about two and a quarter), that had not changed for the worst in the least. One year ago this month some of my emulsion was sold to a gentleman going to Brazil, S.A. He bought two half-pound bottles, and one of them he brought back unused early in last September. Mr. Price obtained it from him especially for me to try. Mr. Price made some dry plates with it, and requested me to try them. I here show some pictures taken in the Park instantaneously on those plates, and others, prepared by Mr. Price. They were not intensified at all, but are just as they were developed and fixed. I made three portrait negatives, two of which are now exhibited, with this emulsion exposed wet. It was not quite so sensitive an emulsion as they are making now, but these negatives were made in six seconds under an unfavourable light. The negatives and prints were all that could be desired, and were pronounced by those present to be *perfect*.

Dr. HIGGINS: I find in the way of instantaneous photography that with any really good, decent emulsion—such as the present time gives us—there is not the least trouble in taking an instantaneous view. I have been in the habit since last spring of almost daily taking the various steamers that pass my house. An exposure of the twentieth of a second by calculation is sufficient. At the next meeting I will most likely bring you prints of steamers taken as late as five o'clock—it is almost dark at that hour now—with an exposure of the twentieth of a second. There is a very marked difference between the negatives shown here by Mr. Newton and my negatives—instantaneous ones. I can only attribute it to his fixing with cyanide, instead of with hypo.

Mr. NEWTON: No, that is not it.

Dr. HIGGINS: My negatives have not that appearance. Those have the appearance of the ordinary bath plate, whereas my emulsion always gives a very strong, black image, very intense. I did not know but what you fixed it in cyanide, because that changes the colour.

Mr. NEWTON: I sometimes fix in hypo, and sometimes in cyanide; but I dislike to get hypo. on my fingers when I am experimenting with emulsion. The appearance of the negatives is the same, whether fixed with cyanide or hypo.

Dr. HIGGINS: In the matter of development of emulsion plates, the quantity of bromide necessary is dependent entirely upon the particular character of the emulsion and the way in which it is compounded. Every emulsion requires to be properly adjusted,

* We understand that the prints exhibited by Mr. Cooper were such as are elsewhere designated Artotypes, made in fatty inks, and by means of a press.—Ed.

and a special developer. With my emulsion I can only use my developer—the one you see here. I can keep it on the plate an hour without fog—it is impossible to fog with it; it would simply give more and more intensity. Mr. Newton makes a developer to agree with his emulsion, and I understand that my developer does not work well with his emulsion, and I know that his developer upon my emulsion plates will fog. Aside from the point that every emulsion requires its own particular developer, there is this to be stated. If upon the exposure of a plate you take the developer (I will speak of mine for my own emulsion plate), and instead of using at the ordinary strength, which is very weak, as you can see, you simply take half an ounce of water, and add two or three drops of the developer to it, it will give you a beautiful development, very slow; and although sufficient intensity is gained by that weak condition of the developer, your image will be of an exceedingly soft character—too much so. If, on the other hand, on the same normally exposed plate you use my ordinary developer, but make it double the strength, the image will flash out as quick as a bath plate, and the resulting picture will be very strong and harsh, with a great want of fine details. But this is an exceedingly good development for lithographic purposes, where strong contrasts are required; and so, by varying the character of your development, you can give every desired character to the emulsion plate. I care not what the composition of that emulsion is, whether it is bromide or bromo-iodide, if the emulsion works too soft or too harsh, vary your development, and see what you will get.

Mr. NEWTON: I should not agree with the Doctor in his conclusion that every emulsion requires a particular development, or developer, rather. As a rule, the alkali developer is the developer, and the carbonate of soda is becoming the most frequently used alkali. I now have some three hundred samples of emulsions, compounded with various and all heretofore used salts, and many which I have never known to be ever used, and compounded in a great variety of ways, and on all of these the carbonate of soda developer works well. Now the amount of bromide that is put in, and the strength of the alkali solution, of course, will vary the result; but there is one fact that I have observed that I am not aware has been observed by others, which is, that an old emulsion requires very much less bromide than a new one in the developer. Take an emulsion a year or two old, and you need not use so large a quantity of bromide. But whether the developer which the Doctor calls his would develop my emulsion, I don't know, but I have no doubt it would. I have never tried it, and if the Doctor has, he knows. When I originally gave the carbonate of soda developer to the Section, I exhibited a large number of negatives developed with it. The formula which I then gave I stated was used in developing these negatives. I also stated that it could be used with any modification of the given strength, varying with the time of exposure or effect desired. I also stated that I had used it as strong as eighty or ninety grains to the ounce, and further that the action could be greatly accelerated by the use of ammonia, the formula for the use of which I then gave.

Dr. HIGGINS: I don't dispute the power of sal-soda to develop any emulsion plate. I simply am of opinion that the quantity of sal-soda and the quantity of restraining bromide in an alkaline developer is with good result varied to suit different emulsions.

Mr. NEWTON: The point, as I look at it, which makes the developer act is the exposure. If the image comes out slow and hard, and lacks detail, there is some fault either in exposure or developer; that is all. If your exposure has been right, you will get detail in the shadows by proper development.

Mr. DUCHOCHOIS: With the same exposure you will find that two developers produce entirely different pictures; the one will be black and white, and the other full of detail. I agree with Dr. H. that, with a particular emulsion, you must have a particular developer.

Mr. NEWTON: It is just the same with a bath plate.

Mr. ROCHE: I had some Liverpool dry plates. I tried Newton's developer without satisfactory results. I then tried the developer made according to the formula sent with the plates. They then came out fine, soft, and full of detail. I think Dr. Higgins is right.

Mr. NEWTON: A reverend friend of mine from a neighbouring city bought twelve dozen of those Liverpool plates, and followed the printed instructions exactly in developing, and got nothing worthy of the name of a negative. He tried the carbonate of soda, and they were very sensitive, and made as beautiful a negative as you ever saw. This is simply an illustration of an oft-recurring anomaly, where quite different results are obtained by

different persons using the same photographic compounds. The gentleman referred to, in order to further satisfy himself in regard to the action of the soda developer on the Liverpool plates, brought some of them to my studio for me to expose and develop, which I did with equally satisfactory results.

Mr. ROCHE: Don't you modify your developer to suit the exposure?

Mr. NEWTON: Of course I do—stronger or weaker, with either more bromide or more soda.

Mr. DUCHOCHOIS: It would be better to decrease or increase the amount of bromide.

Mr. NEWTON: You want more bromide to develop a dry plate than a wet one.

Dr. HIGGINS: I don't think there is any difference at all between the President and myself. The President varies the proportions of alkali and bromide to suit individual exposures, and I, of course, agree that he is correct there. I, however, go a step further, and say that when you can have a developer which needs no alteration in any shape or manner in the proportions of the ingredients for the different exposures, that we have got a more desirable developer.

Mr. NEWTON: If there is a developer that will produce uniform results without much reference to exposure, that I admit would be desirable; but I can take a wet or a dry plate, like those I exhibit here—here are two, one exposed thirty seconds and the other fifteen, and one equally as good as the other, and both developed with precisely the same developer. That latitude you have not got in working a bath plate; but that latitude can be carried still further by varying the strength of your developer, so that you can expose the plate fifteen seconds or a minute, and get equally good results. In reference to the keeping qualities of emulsion, that is a very important thing. This instantaneous plate was made with emulsion that had been to Brazil, S.A., and remained there through the winter, and was brought back in the month of September. Those two portrait negatives were made with it in about six seconds; so you see that it is not changed for the worse, and, if anything, it has improved. I have emulsions now that will be three years old in November. The last time I tried them they were two and a-half years old, and worked satisfactorily. I presume the doctor will corroborate me in reference to the keeping qualities of emulsion. Having it so that you can use it any time within a year, or two years, you can feel sure that you have something that you can make a good picture with.

Dr. HIGGINS: In the absence of organic matter and free silver, I believe that an emulsion will keep indefinitely. I find it to keep for years without free nitrate or organic matter introduced into the emulsion.

Mr. NEWTON: This emulsion that I have just spoken of, nearly three years old, I put into every ounce two grains each of pyrogallie acid, tannin, and gallic acid—that at the end of two years made as beautiful negatives as I have ever seen.

Dr. HIGGINS: I said that with the absence of organic matter and of free nitrate of silver, I believed an emulsion will keep indefinitely. The President will certainly agree with me there.

Mr. NEWTON: Certainly.

Dr. HIGGINS: The President goes further, and thinks that the absence of organic matter is not necessary.

Mr. NEWTON: I am stating the fact.

Dr. HIGGINS: I, myself, should be afraid to trust an emulsion with organic matter. The only way in which I think it could have happened was that there was a large amount of silver used, so that the organic matter was taken out by the quantity of silver and rendered inert, and the emulsion left, as it were, without it.

Mr. NEWTON: The organic matter in that case was put in after the free silver had been converted into a chloride. I might as well state, in reference to the organic matter, that these plates exhibited were made from the emulsion that went to South America, and which was strongly organified; that there is a large quantity of organic matter in it, and it is not necessary to add anything more. Flow the plate, and wash it in clean water, dry, and it is ready for exposure.

Dr. HIGGINS: If that emulsion is organified, why do you wash the plate after flowing it previous to exposure?

Mr. NEWTON: Do you mean to ask me whether it would be just as good without washing?

Dr. HIGGINS: Yes.

Mr. NEWTON: Well, I have not tried it.

Dr. HIGGINS: The only object of washing, as I understand it, is to get rid of the soluble salts, and, in doing so, to organify the plate by the organic matter in the water.

Mr. NEWTON: I have not tried that emulsion in that way. I agree with you that the washing is a good thing. My opinion is that washing is a first-rate thing for emulsion dry plates.

Mr. DUCHOCHOIS: The washing of the emulsion was absolutely necessary to obtain great sensitiveness, by removing the soluble nitrate, which interferes with the action of the light, especially the blue rays.

Dr. HIGGINS: I disagree with Mr. Duchochois on that point; for if an emulsion film was flowed with alkali and tannin, exposure and development would result in every way as desired, and in such case no soluble salts would be removed.

The meeting then adjourned.—*Anthony's Bulletin.*

To Correspondents.

W. W.—You will already have obtained the details you require regarding the rapid process from M. Boissonas' letter in our last. We believe that the gilding of the edges of cards is always effected with gold leaf, how far pure we cannot state. So far as we know, bronze powders would not be available for such work. As we stated last week, we found no enclosure in your letter.

C. HOOD asks for information as to the most profitable method of disposing of 20,000 quarter-plate negatives, and as to the probable amount of silver to be obtained from them. The question is a new one, upon which we have, unfortunately, neither information nor experience. Can any of our readers supply suggestions? In the absence of data, we can only suggest removing the films by means of a hot solution of soda, and then ascertaining the amount of silver in a hundred for experiment. The whole question, it seems to us, must be determined by experiment.

A. (Notting Hill).—Your best plan will be to write to Mons. Ernest Laean, 21, Avenue de la Grande Armee, Paris, stating your wishes. He can probably give you the best information on the subject, or, failing that, his journal, the *Moniteur de la Photographie*, is the best journal in which to advertise your want.

A. MANDERS.—If you have a magic lantern you may use it to throw an image on a screen of canvas or paper, using the negative as a slide; or, failing that, the process is very simple without a lantern. Make a frame to fit your camera in place of ground glass. In this frame must be an aperture the size of the negative, in which the latter must be fixed. Place this so that the light from the sky passes through the negative and through the lens, and is received on a screen placed a sufficient number of feet behind the camera, moving the screen, and focussing the camera, until the image is sharp and of the proper size. The remainder of the window should be darkened so that the principal of the light, if not all, which enters the room shall be that passing through the negative. You will find the operation simple enough in fact, although it is not easy to describe very clearly in the limited space of an "Answer to Correspondents."

B. B. R.—The YEAR-BOOK will be ready in a few days, and will contain full information on both the subjects you name.

L.—It is difficult to say what is the best method of warming the dark-room. An open fire is dusty, as is also a coke stove. A charcoal stove is dangerous, and should not on any account be tried. The fumes of carbonic acid given off would soon prove fatal to life. A gas stove must have some method of carrying off the products of combustion. One of George's Calorigens is really the safest, cleanest, and most wholesome means of warmth you can use, and gas supplies the heat. The temperature of the room should not be below 50°, and should be as near to 60° as possible.

NOVICE.—We should prefer No 1, having found it excellent for the class of work you name.

J. B. BEST.—Various methods have been proposed for making collodion give a more powdery film, in many of which we have very little faith. It is best to begin with a suitable pyroxyline in which the powdery quality has been produced by weak acid and high temperature. Failing this, then ripeness in the collodion gives good results. The addition of water to a tough collodion will make it yield a powdery film; but this requires much care, as excess of water leads to reticulation and absolute rottenness of film. 2. We should certainly not add acetic acid to the bath, and for dry plates a good proportion of bromide in the collodion is of vital importance. The process you name is moderately good. But of all the bath processes, we think the coffee process is one of the simplest and best. The formula given by Mr. Whitehouse in our YEAR-BOOK for 1877 gives excellent results. The old collodio-albumen process is the most certain process we know, but the preparation of the plates is very tedious. Emulsion processes etc, however, superseding bath processes.

Several correspondents in our next.

The Photographic News, January 10, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

A GOOD MOUNTING MATERIAL—THE POISONOUS PROPERTIES OF BICHROMATE OF POTASH—GERMAN JOURNALS.

A Good Mounting Material.—A good mounting material is a blessing to photographers. Gum, glue, starch, rubber, dextrine, flour, shellac, and other materials too numerous to mention, have in turn served the photographer's needs, and solutions of them have various advantages. You do not always want the same kind of mounting material. If it is a thin delicate sheet to be mounted, no one would think of taking thick hot glue, nor when a stiff carbon impression is to be fixed is he likely to employ gum-water. There is, however, something else besides the cementing power of the material to be considered in selecting a substance for every-day use. It may dry too hard, or it may, on the other hand, have such a tendency to absorb water that print and mount part company as soon as they are put in a damp place. A pure gelatine or isinglass is a very good mounting material when dissolved in warm water, but it is hardly suited to photographs. In the first place, it is difficult not to apply too much of it, for the viscid solution clogs the brush; and in the second place, it becomes so hard and brittle that the mount, if it is not very stout, is sure to buckle. Bookbinders and others, for this reason, do not employ refined gelatine or the best glue in their work, but prefer a second-class material, known as town-made glue. This, they find, works up to a froth more readily, and the consequence is, while the solution in this form is more easy of application, there is less of it actually applied, and the consequence is, less chance of exudation when the application is finished. There cannot be anything more annoying to the picture-mounter than to find the material he employs exuding from the margin at the end of his work. This is frequently the case when gelatine in solution is used that is applied more in the form of a syrup than a froth. Some use a mixture of gum and glue, and this is to be recommended in the case of stubborn prints which want a good deal of cement upon them. In all cases where glue is employed, it is necessary, however, to have heat, and this some people object to; while another drawback is, that it buckles the prints if these do not happen to be mounted on thick board. The buckling may to some extent be avoided by the addition of sugar, three or five per cent. of the latter being generally sufficient. But where the mounting is to be done on paper or a thin mount, glue is hardly suitable, and starch or dextrine is to be preferred. One of the best receipts for a mounting material of this kind is one recently given in these columns by "Trywell," of Hawkhurst, which we have essayed with so much satisfaction, that it has been forthwith adopted in preference to any other. It is simple to prepare, and may be employed cold, a feature all the more to be noted, since it contains spirit, which would otherwise evaporate rather quickly. We quote "Trywell's" formula:—

Water	1 ounce
Methylated spirit	2 ounces
Dextrine	2 table spoonfulls

Mix the water and spirit, stir in the dextrine, making a smooth paste, and place the vessel you mix it in in hot water till a clear brown solution results. This solution, we can assure our readers, is a very good mounting material for photographs. The print lies smoothly and evenly without that tendency to buckle which most cements betray. Those who give this inexpensive material a trial will feel grateful to "Trywell" for making the receipt public.

The Poisonous Properties of Bichromate of Potash.—A complaint comes across the sea from America, that sufficient warning has not been given those who practise carbon printing of the deleterious nature of the bichromate of

potash solution with which we have to work. M. Duchochois read a paper at the American Institute, in which he put himself forward as a victim and sufferer of the effects of bichromate, and we can readily believe that the poisonous nature of the salt is in some cases of a most virulent character. M. Duchochois is wrong, however, in supposing that attention has not been drawn to the gravity of the subject, for not only in this country, but in America, has it been referred to, a volume by the Editor of this journal published by Messrs. Anthony & Co. having specially directed readers to the fact. Bichromate of potash solution works upon some systems more strongly than others, but in any case it cannot be without injury to those who are constantly employing the salt. Thus, although to wet one's figure with a solution daily for a few minutes may not harm, it is another matter altogether when a photographer or his assistant does nothing all day long but sensitize carbon tissue in a bichromate bath. To do this, with a stout constitution or a weak one, cannot be beneficial, to say the least of it. It is like collodionising plates. To breathe the ether fumes now and then, when you enter a dark room to coat a plate, may not be injurious; but to be an assistant confined all the morning, doing nothing else, may lead to serious consequences. We have seen this in one of the finest Paris studios—an assistant cooped up near the roof, whose duty from morning till afternoon had to be carried on in a hot cupboard full of ether and alcohol fumes, the only relief being when he momentarily opened the door to hand out or receive the slides. Even supposing the cupboard to have been as well ventilated as possible, the tainted atmosphere must necessarily have been bad to breathe day after day, and we took some consolation, we remember, in the fact that the assistant in question was a man of half caste, and we hoped, therefore, in a better condition to bear the hot close air around him. We cannot help thinking that bichromate solution, however harmless it may appear in some cases, can hardly be employed with immunity day after day without having some deleterious results. It may be argued that as bichromate of potash has been used for coating articles of food—to wit, the pea-sausage to which we adverted last week in these columns—it cannot be strictly considered poison. But the cases are widely different, as will be seen at a glance. In the first place, there is no need of the bichromate to penetrate the gelatine skin at all; the sausage, if first of all covered with a thick layer of gelatine, and then dried, before the application of the bichromate, might not come in contact with the latter at all; but even if it did, the food would be of a greasy repellent character, while at the same time it would lack that absorbent power which a living system represents. There would be no absorbing action constantly going on and carrying the poison into the system, which constitutes the main injury when we dip our fingers into a solution. So that, although bichromate liquids may not act as poison in trivial cases, there can be little doubt about the risk photographers run who systematically wet their fingers with the solution; and we owe our thanks to M. Duchochois for so vividly portraying the effects which may arise from disregarding ordinary means of precaution. No doubt when carbon tissue comes more generally into use we shall be able to purchase our material already sensitised, and thus obviate the danger altogether.

German Journals.—The new German journal, the *Deutsche Photographen Zeitung*, has just completed its first year, under the editorship of Herr K. Schwier, of Weimar. We are glad to make this announcement, since two of our German contemporaries, *Licht* and *Helios*, have long since disappeared. Being printed in Weimar, the headquarters of the *Zeitung* is practically in Mid-Germany, and therefore should be in a good position for circulation. There are now, we believe, two weekly photographic journals in Germany, but their columns are very small compared to the sister periodicals in this country.

NOTES ON THE APPLICATION OF LIGHT.

BY W. W. STODDART, F.C.S.*

No one can have made many delicate researches in chemical phenomena without noticing the very remarkable difference produced when light is present or when light is absent, or the changes that take place in the chemical reagents themselves when one portion is allowed to remain on an open shelf exposed to the influence of light, while the other portion is strictly kept all the time in a dark cupboard, and both in well-stoppered bottles. This is especially seen also when testing with these reagents. A noticeable difference may more easily be seen in the months of April and May, when a full proportion of the actinic rays are present.

It is possible that no ray of white light ever falls on any natural solid or liquid without setting its molecules in an intense state of vibration and producing a peculiar aptitude for change. I am not now alluding to silver salts, or other well-known photographic agents, whose sensibility to the rays of sunlight, the electric spark, or the combustion of magnesium is known, but ordinary inorganic and organic solids. The molecular changes that take place may be quite invisible to the unaided senses, but are none the less potent.

Mr. Lockyer's late observations on the compound nature of the elements in some degree bear out this idea. In a late number of the *Annales de Chimie Physique*, M. Chastaings says that the chemical action of the various rays on inorganic substances is dependent on the refrangibility of the ray—the blue and violet rays acting as reducing agents, while the less refrangible ones, such as red and yellow, cause oxidation. Professor Vogel, however, denies this, and says that reduction or oxidation depends solely on the nature of the object itself. Thus, hydrogen and chlorine unite instantaneously when exposed to the blue and ultra-violet rays, and this, he says, is analogous to oxidation, and alludes to the fact that plants decompose or reduce carbonic acid more rapidly with the red ones.

I must confess I cannot quite agree with the Professor, for I think that it is the light itself which has the peculiar power in effecting a molecular change in the object on which it impinges; but to better express my meaning the following experiment will suffice:—Nearly fill a glass tube with the freshly-ignited sulphides of the alkaline earths, and submit the tube to the various parts of the spectrum. The less refrangible rays will produce no appreciable effect; but no sooner is the sulphide placed under the influence of the more refrangible, or the blue and ultra violet rays, than the superficial molecules are placed in the most intense state of vibration, and on taking the tube into a dark-room a strongly-coloured phosphorescent light is emitted.

Most present are familiar with the autotype or chromogelatine process. The jelly kept in the dark is an ordinary soluble mixture, but when exposed for a short time to the more refrangible rays of light its nature invisibly changes: the high lights, as they are termed, become quite insoluble in warm water, while the middle tints become only partially insoluble, an insoluble compound being probably formed with reduced chromic acid.

If we place a small quantity of ordinary table salt on two white glass-stoppered bottles, and put one of the bottles on a shelf in a light place, and the other in a dark cupboard, it will be found that in a few weeks the salt on the shelf and exposed to the light will become darkened and have a dirty appearance, while the other that has been kept in the dark has retained its former whiteness.

Pharmacists are familiar with the fact that when camphor and similar volatile solids are stored in transparent white bottles, they always crystallise on the side

of the bottle—that is, towards the light. When a *burette* that has contained a dilute solution of silver nitrate for the estimation of chlorides has been well washed out with distilled water, and laid aside in the stand, although so apparently completely clean, a very minute film of silver chloride is left on the glass tube, which gradually becomes visible by its change into a dark violet colour on exposure to daylight. A drop of the distilled water that remains after washing out of the *burette* will, on being tested, show that the molecules of metallic chloride have been changed into a subchloride and chlorine—

A similar reaction takes place with the bromide or iodide—

The molecular disturbance is rendered far more active if a gentle heat be applied.

If a piece of white silk be dipped into a solution of auric chloride, and, while moist, exposed to light, the silk will become greenish, then purple, while afterwards the metallic gold itself will be precipitated on the surface. An alcoholic solution of a vegetable substance is usually thought to be perfectly well preserved, and a most permanent preparation—indeed, the most stable of medicines. It is so if kept constantly in the dark, but in daylight a singular change will take place.

When the leaf of a biennial plant of *Hyoscyamus* is macerated in proof spirit and filtered, an extremely beautiful and well-marked spectrum is seen when viewed under a micro-spectroscope. Several well-marked absorption bands appear at B, D, E, and F. Even if kept in a well-stoppered bottle and exposed for a few months to ordinary daylight a molecular change takes place, although quite imperceptible to the unaided eye; but under the spectroscope the absorption bands are altered, and their number and characteristic position are seen no longer.

A still more remarkable instance of the powerful action of actinic light is shown when a few chips of common logwood are macerated in rectified spirit. When the alcoholic liquid is made with freshly-cut wood it has a yellow colour, and is wonderfully sensitive to ammonia, potassium, and other alkalies, and produces an exquisite blue with alumina. But when this liquid is kept in ordinary daylight for a few months a most extraordinary change is found to have taken place. The tincture is no longer sensitive to these reagents, nor will it form a blue compound with alumina. In the first instance the hematoxylin loses two atoms of hydrogen, and another body called "hematein" is formed, which readily unites with ammonia and the different bases. In the second instance the light has affected the hematoxylin in a way not hitherto perfectly explained, so that the actinic rays have not only produced a molecular, but a chemical change.

It is to this state of quiet and imperceptible action that many puzzling photographic failures are due, and I fully believe that were photographic reagents prepared and kept all the time in the dark, as carefully as sensitised paper, a strongly-marked difference would be found in the results. If, then, so great a difficulty is experienced in the wet processes, how much more may be expected with dry plates! I think it is the general opinion of all photographers that, for some unexplainable reason, if kept for some time without being used, the proper development of a dry plate is often a matter of great uncertainty.

Another very remarkable fact occurs when a perfectly colourless solution is intensely opaque to the chemical rays of light; for instance, a solution of the vegetable alkaloids or glucosides is perfectly opaque to photographically useful rays of light. If placed in front of a sensitized plate a layer of solution will as effectually stop all photographic action, even if exposed for a considerable period, and the expected photograph will sustain as complete a blank as if a thick plate of copper had interfered.

* Read before the Bristol and West of England Amateur Photographic Association

RECENT ADVANCES IN THE APPLICATIONS AND SCIENCE OF PHOTOGRAPHY.*

It is, perhaps, as a handmaid to science that photography gains its greatest lustre; for, though a science in itself, it is chiefly in connection with chemistry and physics that it obtains the fullest recognition. Artists in public affect to despise it; though in private it has become an invaluable aid to them; but scientists are always ready to acknowledge its utility, hence to science rather than to art it has to look for due acknowledgment of its claims. A quarter of a century ago photography was the nursling of such men of genius as Sir John Herschel, Becquerel, and Draper; and as phenomenon after phenomenon was discovered it attracted a large share of attention from the scientific world; but when the collodion process of Archer was announced and practically introduced, and it became open to the meanest intellect, it was deserted by our great thinkers, and as a science made but little progress till recently. A revival of the interest which once existed in its growth in this respect occurred some three or four years ago, when Dr. Vogel and Captain Waterhouse demonstrated that there are fields for exploration in it yet open to him who might wish to work. They showed that the yellow and green rays of light, which were ordinarily supposed to have no chemical action on the most sensitive silver compounds, could be utilized for obtaining photographic impressions, by staining the collodion film with different aniline dyes. Following their steps, Captain Abney has shown that not only all the visible radiations can make an impression on a simple silver compound, but that the dark rays of low refrangibility, the existence of which was previously known solely by their thermal effects, can be similarly effective when the simple compound is so prepared as to absorb these radiations. Here we have a possibility of extending our knowledge of spectrum analysis, as we shall presently show, and of solving problems which heretofore were impossible to grasp. Another advance in deciphering the work written by light has also been made, which sets at rest the notion that existed regarding the properties of the red and the blue rays of the solar spectrum. Draper had noticed and Herschel had confirmed the fact that the former had apparently the property of undoing the work which had been performed by the latter on the sensitive silver compound, iodide of silver—with which photographers are familiar—that is to say, that if a picture were taken with the blue rays, or with white light, and then were exposed to the action of pure red light, the work of the first-mentioned rays would be undone. Thus Claudet found that a red sun was photographed as a black object against a white sky, notwithstanding the sky itself intervened between his lens and the sun. This antagonism of the different components of light remained a mystery till quite recently, when Abney was able to show that the phenomenon was due to the oxidation of the compound, which had been altered by the blue or white light, such oxidation preventing the development of the photographic image. The outcome of this last solution may, perhaps, have important results, as we find that photographs in natural colours may be produced by this process of oxidation, and if it be only possible to render them permanent, the long sought after Eldorado will be reached.

Such is a brief outline of the progress made in the science of photography itself; but the applications of it to other branches of science are very numerous, though we can but recount some few. In solar physics we find it employed at the Physical Observatory of Meudon, near Paris, by Janssen, on a larger scale than has hitherto been attempted. In his photographs of the sun exhibited last year before the British Association, we find its surface shown of the enormous size of twelve inches for a diameter, with details of structure which have never before been seen by the eye. These magnificent records of our luminary are due to the skill of Janssen in modifying existing processes for his purpose, to perfection in the telescope employed, and to the minute fraction (1-3000th it is said) of a second during which the image is impressed. In these pictures we can trace the movement of the solar tornadoes in the photosphere by the obliteration of its definite structure, the very form of which would have remained open to doubt had visual observation alone been open. The telescope, it is true, when armed with a high power eyepiece, shows the mottled appearance of the solar surface, but the area in the field of view at one time is limited, owing to the necessary magnification, and we should never have learnt by it that these

solar storms were aught but the speculations of the theorist. In the photograph we are able to examine the surface as a whole, and to follow the track of the disturbances at our leisure. With the eye we integrate the solar atmospheric disturbances which occur in about the 1-10th of a second, in the photograph we have an integration for the 1-3000th of a second; visual observations are evidently, therefore, heavily handicapped compared with the photographic. For many years past we have had smaller photographs of the sun produced at Kew and Greenwich by the aid of De La Rue's photo-heliograph, with the view of obtaining an accurate register of the sizes and form of the solar spots, which wax and wane and wax again in number about every ten and a-half years. If famines and want of rainfall have anything to do with the absence of sun spots—and it seems more than probable from statistics that they have—it is principally to the photographs we must look to furnish the proof, and by them the theory must stand or fall. The establishment of a small observatory in India, where the sun is more frequently seen than it is in England, for the purpose of obtaining auxiliary photographs to those at home, is a step taken in the cause of science, and in all probability for the benefit of humanity.

The same form of instrument with which these smaller photographs are taken was employed by the English expeditions for recording the transit of Venus over the solar disc, and though the parallax obtained by photography has not proved to be as satisfactory as it was hoped, yet the fact of its employment at all marks the value set upon its aid by astronomers. In the recent total solar eclipse visible in America, it again obtained recognition as a recorder of facts in contradistinction to the eye, which is sometimes a recorder of foregone conclusions, and we find that no party of observers was complete without its camera and its photo-spectrograph.

Turning to another important and rapidly growing branch of physics, we must note its adaptation to spectrum analysis, in which Draper, Lockyer, Vogel, and Cornu, among others, have given it full employment as regards the sun, and Huggins as regards stellar work. During the last few years some of the most important advances in solar analysis have been made by its aid. Thus we find that Cornu has mapped the ultra violet region of the spectrum, and in that portion bordering on the region of visibility Lockyer has been able to lay down hundreds of those dark Fraunhofer lines which cross the spectrum and tell us of the constitution of the sun, while visually the number might be reckoned as units. Not that the absolute number is so important as the fact that some of the new ones mapped disclose the existence of elements in the solar atmosphere which before were more than doubtful. Again, too, in the spectrum photographs a leisurely study can be made of the relative thickness and darkness of these Fraunhofer lines, and the constitution of the upper and lower layers of the photosphere be approximately determined. It seems probable that even in our own day a change in their condition has occurred, since the relative blackness of certain lines has apparently altered. In future years the testimony of our photographs will be more valuable than the records of one hundred eye observations. We cannot do more than give a passing allusion to Lockyer's great discovery of the long and short bright line of the spectra of metallic vapours and their connection with the spectrum analysis of the sun, and of the possibility of reducing each of the spectra to one distinctive line, or monochromatic colour, in all of which photography has played an important part. By photographing the dark regions of the solar spectrum of low refrangibility, we may hope to know more regarding the state in which some of the metals exist in photosphere, since experiments made with the electric arc have shown that if they do so as compounds their spectra will partially lie in this part. Huggins, in his photographs of stellar spectra, shows records of the truth of the dictum that we have hot and cold stars planted in the heavens, and possibly they may tell us a good deal more than this as our familiarity with them increases and as our means of interpretation grow. To Francis Galton we are indebted for a totally novel application of photography to scientific research. By taking photographic portraits of our gaul birds, and then building up a picture with the photographs of convicts imprisoned for the same class of offence, he is able to show us the type of face and head from which we may expect the commission of any particular crime. Or, again, by taking the photographs of a family, and giving a certain value to collateral branches, he is able to build up a typical family face. The combination of these portraits, we may remark, is effected by

* Continued from page 4.

printing the camera pictures on the same paper for different lengths of time. Thus the son's portrait might have three minutes' exposure to light given to it; this camera picture would be withdrawn, and a paternal uncle's superposed for one minute, and so on, till the whole family had contributed to make the typical face. Some of the results obtained are immensely striking, and we doubt not that much more may be learnt by adopting this or some other similar method for the purpose. At Greenwich, and at other meteorological observatories, we have long had photography employed as the registrar of the slow variations indicated by various meteorological instruments, but to-day we find it put into requisition for the registration of quick oscillations. The vibrations made by the disc of the telephone, the movements of the pulse, the forms of beats—all of them are now recorded by it; and we might indicate other branches of science where the rapidity of the impressions made would be of immense value.

In our military services we have it employed as a measurer of the force of torpedoes, by registering the height and dimensions of the volume of water raised, or as a reconnoiterer from a balloon. At the siege of Paris we all recollect the pigeon post, and the use that was made of it for sending despatches and letters in miniature; but we shall be surprised if in a future war photography is not used more extensively than at present the public think possible. Our list might be lengthened out if space permitted; but we have, we think, shown sufficiently that photography progresses in itself and in its applications, that it is a scientific industry as well as a science, and that its future is not a contracted one, but universal in its character. Light must become the pen of the man of science, the pencil and colour-box of the artist, and the tool of the engraver.

ON EXTREME RAPIDITY BY THE USE OF THE WET COLLODION PROCESS.

BY CHARLES WALDACK.*

It was my privilege, two years ago, to receive a visit from Mr. Boissonnas, of Geneva (Switzerland), and to examine his album of pictures made by his rapid process. The pictures astonished me greatly. The evidence was there that they had been made by very short exposures, and I felt convinced at the time that Mr. Boissonnas had succeeded in modifying the wet collodion process so as to make it a great deal more rapid than when the various ordinary formulæ are used. A short time afterwards an intimate friend came into possession of the secret process, compounded collodion, bath, and developer, and invited me to witness a trial of the new chemicals. I went provided with collodion, bath, and developer, all freshly made. Tested against a set of chemicals which had been in use for some time, the advantage was decidedly in favour of the Boissonnas compounds; but when tried side by side against the newly mixed chemicals I had brought with me, the results were similar. 'Tis was a disappointment, for I had worked myself up to the point to believe that a great progress had been made, and that we had a new power in our hands. Subsequent experiments went to confirm the first, and the only conclusion I could come to was that the astonishing results obtained by Boissonnas were due, not to the extreme sensitiveness of the compounds used, but to very favorable conditions of light and clever management.

A closer examination of some of the Boissonnas specimens proved that most of the subjects, children, dogs, and cats, had been perched on a table or platform, so as to bring them closer to the skylight. The illumination had been managed, not with a view to effect, but to rapid action. The rule, expose for the shadows, and the lights will take care of themselves, had not been forgotten. High shadows require short exposures. Thin negatives are thus produced, which have to be brought up to printing density, hence the necessity for redeveloper and intensifiers. The result is a certain granularity of deposit, and, to some extent, an obliteration of half-tones. The Boissonnas prints are by no means fine

specimens of photography, but they are evidence of great rapidity of action.

Now, if your readers wish to know how the collodion, bath, and developer had been made, which proved equal in sensitiveness to those recommended by Boissonnas, I will give in a few lines the manner of compounding them. I must say beforehand, however, that I do not believe them to be more sensitive than many others which they have, or may have had, in use. Pure materials, and such there is no difficulty in getting at the present time, are the main thing. The substitution of one iodide or bromide for another (I speak of those generally in use), has very little influence on the result, if the collodion be used at the proper time. The ether should be pure, free from foreign smells, not ozonized; the alcohol free from essential oils. All our respectable stockdealers supply us with everything in the best condition. Do not rely on the country drug store.

Plain Collodion.

Alcohol...	...	¼ litre (250 c.c.)	(10 ounces)
Pyroxyline*	...	(10 grammes)	(300 grains)
Shake and add			
Ether	½ litre (500 c.c.)	(20 ounces)

Shake until complete dissolution, and let settle.

Iodizing Solution.

Alcohol...	...	¼ litre (250 c.c.)	(10 ounces)
Iodide of ammonium	...	(10 grammes)	(300 grains)
Bromide of ammonium	(4	,,	(120

Filter. To three parts in volume of the plain collodion, add one part of the iodizing solution the day before using. In hot weather do not prepare more than you want to use in the next two days. The ripening process, if pushed too far, is detrimental to sensitiveness.

Silver Solution.

Fused or recrystallized nitrate of silver	90 grammes (3 ounces)
Distilled water	1 litre (36

Use as good water as you can get; distilled, or water from clean and pure ice.

Filter. Keep one-fourth of the solution apart, and to the rest add a couple of crystals of iodide of potassium dissolved in water. Shake and filter again in the light. If any organic matter should be present it will combine with the precipitated iodide. Throw in your filter about one gramme (30 grains) of nitrate of baryta. After filtration of the iodized part, add the one-fourth which has not been iodized, and acidify with one drop of C. P. nitric acid.

The nitrate of baryta is added for the purpose of preventing pinholes. How it acts I cannot explain; certain it is that it does have that effect.

The developing solution for rapid exposure should be strong, and should not contain more than the necessary quantity of acetic acid to obtain clear pictures. A seven or eight per cent. solution (2 to 30 ounces of water) will be found to allow of a shorter exposure than the ordinary three or four per cent. generally in use. Add two per cent. of the ordinary acetic acid (No. 8), and the same quantity of alcohol.

The collodion and developer can be mixed every few days. The bath, however, will, after a time, cease to give the best and most rapid results. When the developer begins to creep instead of flowing evenly over the plate, boil the bath down to one-half, and replenish with distilled water. A time will come, however, when the loss of sensitiveness will be such that a more radical remedy has to be made use of. The solution should be boiled down to dryness, and fused. The fused silver can then be used to make a new solution, which it will be useless to iodize, however. A good plan, which is used by some careful English workers, is to make use of two baths. The first one alone is used until the developing solution begins to creep; when this happens, the plate is

* *Monies*, 1879.

* The cotton I used was Poulence & Wittman's. That of Anthony's and Hance's or Peter Parys', are fully up to the mark.

dipped for a half minute in a second and new bath. The second bath need not be stronger than five per cent., about 25 grains to the ounce.

A few remarks now about evaporating silver solutions and fusing. The evaporating dishes imported in this country are of poor quality and very liable to crack. The real Berlin dish is difficult to find. Never expose your evaporating dish to the direct flame of gas or coal oil. To use a sand-bath is a very tedious process. Procure a piece of wire gauze, and interpose it between the flame and bottom of the dish. Be very cautious when you use a new dish; heat very gradually. When it has been used some time it is tempered, and will stand the heat much better. Use a large dish for evaporating, and when the mass is very thick and solidifies on drying, put it in a smaller dish to fuse it. Evaporate without bringing the solution to a boiling-point. This is the safest plan. When fusing, cover the mass with a thin funnel, to prevent the projection of fine particles of silver all over the room.

PHOTOGRAPHIC ENGRAVING.

BY CAPT. J. WATERHOUSE, B.S.C.*

Electrotyping Methods.—In nearly all the electrotyping methods the printing plate is obtained by depositing copper on a gelatine relief obtained by the agency of light, or on a cast in plaster, gutta-percha, &c., taken from such a gelatine relief.

If a dry film of chromated gelatine on a suitable support be exposed to light under a photographic cliché, and then plunged into hot water, the parts acted on by light, being insoluble, will remain on the support in different degrees of relief according to the intensity of the light, while the unexposed parts will be washed away. An image in high relief formed of hard and insoluble gelatine will thus be obtained, from which a cast or electrotype in intaglio may be made.

If, however, instead of using hot water, the plate be plunged into cold water, the gelatine will be found to absorb water and swell up in the parts protected from the light, while in the parts acted on by the light it will only slightly absorb the water, and these parts will thus form hollows. The power of absorbing water will also be found to be in exact proportion to the degree of protection from light. In this case, an image in low relief is obtained, which may also be moulded from, or electrotyped.

Upon these two principles several processes of producing printing-plates both for copper-plate and letter-press printing have been founded with more or less success.

The first process of the kind was Paul Pretsch's "Photogalvanography," invented in 1854. He appears at first to have obtained his plates by coating a glass with gelatine and bichromate, exposing to light, and then washing away the soluble gelatine, and taking a mould of the resulting relief in gutta-percha, from which an electrotype was made in the usual manner.†

This process gave fair results both in line and half-tone, but, owing to the washing away of the soluble gelatine being effected on the side of the film exposed to light, the plates were defective, and required a good deal of touching up by skilled engravers, which vastly increased the expense of their production. The process failed as a commercial speculation.

Almost immediately afterwards, in 1855, Poitevin published methods of obtaining plates from the gelatine reliefs obtained by swelling the sensitive films in cold water. Plaster casts were either made from them, or the gelatine surface itself was metallized and electrotyped in the usual way.‡

This method produced tolerable results, though the prints were always somewhat coarse, owing to the fact that

swollen gelatine will not give the same sharpness as when dry.

Both these processes were more or less unsuitable for reproducing subjects in half-tone—Pretsch's because in the process of washing away the soluble gelatine the lighter half-tones were liable to be lost—Poitevin's because of the difficulty of keeping the swelling in proper relative proportion, owing to more absorbent parts of the film lying underneath less absorbent parts. Both processes also failed to give the necessary grain, without which the proper inking of the engraved plates could not be effected.

Various attempts were made to improve on these processes, unsuccessfully, until M. Placet showed that it was necessary to adopt in them the same principle of exposing on one side of the gelatine film and developing on the other, which, as we have seen, had previously been shown to be necessary for the preservation of the half-tones in the pigment-printing process, and for a similar reason.

M. Placet indicated several ingenious ways of obtaining his results.* They may, however, be briefly summed up as follows.

A film of chromated gelatine is exposed under a transmitted positive cliché, so that the light acts on the under side of the film; this is done either by covering the collodion side of the cliché itself with the sensitive coating, or by using a thin transparent sheet of transfer collodion or mica as a support for it. After exposure to light, the film is soaked in water, whereupon those parts which have been protected from the light swell up in proportion to the amount of the action of light upon them. By treating the mould in relief thus obtained with metallic solutions, an electrotype copy in copper may be produced, which can be printed from in the copper-plate press.

If a negative cliché is used, the unaltered gelatine must be dissolved, or a second electrotype must be made.

M. Placet also suggested the employment of a sensitive surface which would become soluble under the influence of light, such as a mixture of gelatine, or other colloid, with perchloride of iron and tartaric acid, as recommended by Poitevin for pigment-printing. In this case the solvent acting on the exposed side hollows out the image in the same way as an etching fluid does on copper, but with the advantage that each line has only the exact strength given to it by the intensity of the cliché; or the altered parts of the gelatine film may simply be swollen with cold water, producing an image in relief. In either case, a mould is taken from the gelatine and electrotyped, or copper may be deposited on the gelatine itself.

By his process M. Placet was able to obtain very perfect gradation of shade in the half-tones of his pictures, with a fine natural grain produced by some means which he did not divulge. He has lately, however, described a method of producing the grain, which consists in plunging the gelatine plate into a solution of bichromate of potash, and then treating it with a solution of protosulphate of iron containing acetic acid.‡ The principle he lays down is first to treat the gelatine with a solvent, and then with a solution of some substance that will tan or contract it.

Messrs. Fontaine, Avet, and Drivet have also proposed similar processes, in which they have partially overcome the difficulty of obtaining a proper grain by interposing between the cliché and the gelatine film a fine network or an impression of an engraved or roulette tint; but these artificial grains have a disagreeable effect, and the methods seem to have fallen into disuse, except for line-work and photo-typography, which will be described further on. Avet's process is, however, I believe, still in use for producing the maps of the Italian Survey.

THE FORTHCOMING DRY-PLATE COMPETITION.

THE time is near at hand when intending competitors for the prize of £50 offered by Mr. Paget for the best dry plate process should be making progress with their preparations. Two finished negatives, which, it is needless to say, should be good ones—as good, at least, as the process will produce—together with three prepared unexposed plates, and a description of the process, must be delivered to the Committee of Award before the end of March. Hence it is quite time that intending competitors should begin to give attention to the subject.

At no former period in the history of photography were dry plate processes so much in the ascendant as at the present time. At no previous exhibition of the Photographic Society were so many dry plate pictures exhibited, and never before was there any approach to such prevalent excellence amongst dry plate pictures. But it is somewhat doubtful whether the forms of excellence exhibited come exactly within the conditions demanded in competing for Mr. Paget's prize. The primary aim in these conditions is not difficult to ascertain. A good tourist's process is manifestly aimed at. The standard of final excellence must not be inferior to that attained by wet collodion. But, apart from that, good keeping qualities before and after exposure seem to be most prominent amongst the indispensable qualities. The prepared plates must keep at least four months before exposure, without deterioration; and they must keep three months after exposure and before development in any climate. These conditions essentially point to plates for travellers. The characteristics of recent dry plate developments have been noticeable in extreme sensitiveness and delicacy of result, rather than in keeping qualities. The boast has been, that the modern dry plates were as good for studio work as were wet plates; and in such a case keeping qualities are scarcely thought of. Amongst the old dry processes there are many which are simple in preparation, fairly sensitive, and excellent in result, but few in which the keeping qualities are beyond question. The tannin process, which had a transient vogue, essentially failed in this respect. The plate, if kept after exposure, gradually lost the latent image produced by exposure. The Fothergill process had a similar fault. A plate which had been kept some time required a longer exposure; and if kept after exposure, required prolonged and energetic development. The morphia process, which was very simple, and gave good results, had practically no keeping qualities. One process alone, the oldest and best of the old processes, had, in combination with many other excellent characteristics, good keeping qualities as well: as the collodio-albumen process scarcely ever failed in any desir-

able quality. In its normal state of working it was not quick, but with hot development it could be made so. It gave fine harmonious pictures, and with a final wash of gallic acid, its keeping qualities seemed almost indefinite; plates in many cases having been kept without any perceptible deterioration for upwards of twelve months.

Some of the modern emulsion processes were found to fail in keeping qualities, and of some others we as yet know little of their capacity in this direction. But we glean from the experience of Mr. Cooper, as stated in his recent paper, that the emulsion process which produced his very fine pictures at the last Exhibition possesses keeping qualities of a rare order. Five months in some cases before exposure, and three months in some cases after exposure and before development, leave little to be desired in this direction. As it is to be hoped that this process may be found amongst the competing methods, it is not desirable to speak more of it at present, beyond referring to it as indicating desirable possibilities amongst emulsion processes.

The committee entrusted with the examination of the competing processes will have no light task in working the various processes; keeping, exposing, and developing the competing plates, &c. There is one of the conditions which can, we think, have scarcely received full consideration when it was published. The plates are to keep well for a given number of months, *in any climate!* Will some member or members of the committee travel with the plates from China to Peru, from the Poles to the Equator? Or will they send the plates travelling to be submitted to this ordeal? Will they be submitted to the wet period of India, the simooms of Arabia? Will they be sent on an Arctic expedition, and made to "cross the Line" to acquire ripeness, like Madeira wine? We imagine not. This phrase "in any climate" has manifestly been allowed to creep into the conditions without thought. The aim, probably, is to imply that the plates must possess sufficient robustness of constitution to travel reasonably without hurt, not requiring, like a patient with bronchitis, to be immersed in a temperature not exceeding nor falling below 65° Fahrenheit.

Such an examination as the committee contemplate demands time, manifestly; and we can scarcely hope for the publication of a decision much within twelve months, if, indeed, it does not exceed that time. For ready reference, and as a reminder to possible competitors, we here repeat the general conditions of the competition:—

"1. The description of each process accepted in competition shall contain sufficiently accurate details to enable any ordinarily skilful photographer to produce results thereby, equal to those obtainable by the wet collodion process.

"2. Sensitive films made by the process shall remain without perceptible change for not less than four months after preparation, and must keep satisfactory three months in any climate between exposure and development. Should more processes than one fulfil the stated conditions, the preference will be given to the most sensitive and easily prepared.

"3. Each competitor, or his representative, shall have the option and be willing, if required, to prepare any special chemicals or appliances, and with such, or others prepared according to his formulæ, make, expose, and develop some negatives by his process, in the presence of the appointed judges.

"4. A description of the processes shall be sent to the Secretary of an Award Committee, to be appointed by the Council of the Photographic Society of Great Britain (competitors not being eligible to act thereon), on or before the 31st March, 1879, accompanied with three 8½ by 6½ inches unexposed plates, and two or more finished negatives. Should the negatives not be equal in the opinion of the judges to those produced by the wet collodion process, they, together with the unexposed films, and descriptions of the means by

which they have been produced, will be returned on or before the last day of May, 1879. Competitors may send the negatives, &c., accompanied with their names and addresses enclosed in a sealed envelope, and marked outside with a cipher and an address, which will be returned unopened, should the Award Committee consider the specimen negatives below the requisite standard of excellence. One or more of the negatives by the successful process shall be retained for exhibition until after the next meeting of the Society.

"5. The decision of the Committee appointed by the Council of the Photographic Society shall be accepted by the competitors as final, and the receipt of the prize shall be deemed equivalent to an agreement that the process may afterwards be published unconditionally, practised by any one. Should the conditions not be entirely realised, the prize may be either awarded or retained for competition during the following year, at the discretion of the judges. After the award the description of the prize and other processes may be published under the direction of the judges, unless a wish be expressed to the contrary at the time of sending in a process for competition, should it not prove the successful one."

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

GELATINE of every kind contains organic salts of calcium, which in the process of incineration are converted into carbonate; the best kinds also contain gypsum. When gelatine is digested in cold water, the calcium salts are dissolved out, as can be proved by testing with ammonium oxalate; sulphuric acid will also always be found in the solution, for the addition of barium chloride gives a perceptible precipitate. The presence of these salts of lime is unavoidable, and as in the chromate processes they produce neither harm nor benefit, it is immaterial, and no criterion of the goodness of the gelatine. The sulphate is also always present in greater or less quantity, but as its presence is equally of no consequence, it is useless, and only an unnecessary trouble to look for it.

The only reliable means of separating alum from gelatine is that recommended by Woodbury and Swan. After softening the gelatine by soaking, it is dissolved in warm water; to every 200 to 250 grammes of gelatine is then added the white of an egg diluted with twice its volume of water, and a few drops of ammonia, the whole being previously well shaken. The mass is then weakly acidulated with dilute acetic acid, and boiled up; by means of the albumen the alum, with a small quantity of gelatine, is precipitated, and on filtering the solution the remaining gelatine comes off perfectly pure. According to the author, however, it is unnecessary to take all this trouble, as, at any rate, the finer kinds of commercial gelatine are never adulterated with alum.

Returning to the consideration of the table, the author observes that the amount of water contained in air-dried gelatine depends principally on the thickness of the cakes and the hygrometric condition of the atmosphere. As shown by the first column of the table, its determination is of no practical value, as the amount of water that any particular kind of gelatine contains bears no relation to its goodness.

Of so much the greater importance is the third column, which gives the "parts by weight of water taken up by one part by weight of gelatine." Although it cannot be said that every sort of gelatine which possesses only a moderate power of absorbing water is bad, it can at any rate not be denied that one possessing a large absorbing power is good. Every gelatine which is able to absorb more than seven times its weight of water at 15° C. will

be found to be reliable for a photographic purpose. But it must not be taken for granted that this is a universal test, for there are excellent collotype gelatines that absorb only five or six times their weight of water. As an auxiliary test, however, the absorbing power of gelatine must not be underrated. The author's experience is that a gelatine rich in gluten, and able to absorb a large quantity of water, gives more easily developable chromate films for carbon pictures and photo-electrotype plates than one which can absorb only a small quantity of water. As an element in the selection of gelatine, this property must therefore not be neglected.

The prime factor, however, in the determination of the value of any particular kind of gelatine is the test of its carrying power. As may be seen in the fourth and fifth columns of the table, the carrying power has a close relation to the goodness of the gelatine. This is shown very clearly in the gelatines numbered in the table one to four, which are of the same manufacture, but of different qualities and prices; as the goodness of the gelatine decreases, so also its ability to bear a weight without tearing diminishes. Just as clear is the evidence given in the table by No. 14 and Nos. 18 to 24; these are manifestly inferior kinds, and can only bear weights that are in a remarkable degree smaller than those which Nos. 5 to 13 can stand, the latter being in other respects of excellent quality. Generally, therefore, we may say the greater the carrying power, the better the gelatine. From the nature of the process by which this carrying power is determined, as above explained, it will be understood that the relative values can only be roughly ascertained. According to the experience of the author the mean error in those values may be taken as 10 per cent.

As has been already mentioned, a gelatine which is well adapted for the collotype process must be able to resist great mechanical pressure, or, which is the same thing, must possess great carrying power. On account of their ability to withstand pressure, Nos. 10 and 11 are specially preferred for collotyping; the table shows that these gelatines can bear a great weight without tearing. The other photographic gelatines are also, according to the table, well able to resist pressure, whereas Nos. 14 and Nos. 18 to 24 can bear a weight of scarcely 450 grammes, and are quite useless for photographic purposes. Generally, a photographic gelatine should be able to bear at least 600 grammes, and one for the collotype process about 700 grammes.

As regards the last column in the table, a jelly consisting of a 10 per cent. solution of gelatine should not melt at a lower temperature than 30° C.; only inferior qualities would do this.

From all these considerations, therefore, the author concludes that a gelatine, to be suitable for photography, must fulfil the following conditions:—It must be colourless, or only faintly yellow; after soaking in water, it must dissolve easily and completely when heated; allowed to lie in water twenty-four hours at a temperature of 15° C., it must not break up; calcined, it should not yield more than 3 per cent., or at the farthest 4 per cent. of ash; lastly, when proved by the method above described, it must be able to bear a weight of at least 600 grammes without tearing. If a gelatine fails in complying with any of these conditions it is not advisable to employ it. When the gelatine is to be used in the carbon process, or in photo-electrotyping, the greatest stress should be laid on its power to absorb water, but if it be required for collotyping, the greatest importance should be attached to its carrying power. For the latter purpose, indeed, if two gelatines show equal ability to resist pressure, the one which swells up least in water should be selected. It should also be noticed that one gelatine will dry with a glossy, and another with a dull surface; the latter is to be preferred for collotype, the former can be corrected by adding spirits of wine.

(To be continued.)

COLLODIO-BROMIDE EMULSION PLATES.

BY WILLIAM BROOKS.

It is now very seldom that we hear of dry plates being made by the old system of collodion and nitrate of silver bath, as collodion emulsions are now well to the front, and at the present time almost every photographer takes an interest in dry plates and the general cry has been how to prepare a reliable dry plate, so that the preparation is not difficult, and the results certain. It is with this object in view that I offer the results of my last year's experiments to photographers, both amateur and professional, which I will give in detail. Many make a sadness of dry plate work. The first question asked is, What exposure shall I give? Well, now, to give the time of the exposure with absolute certainty is a thing almost impossible—the golden rule is to make a few experiments. I will mention one instance. A gentleman amateur asked me to tell him how long to expose a plate for a house, stating its situation, light, &c. I told him what I thought it would require, and he took it for granted that was the proper time for everything, no matter its situation or how the light was. He exposed about three dozen plates. Some were woodland scenes, and, as a natural result, he blamed everybody and everything except himself; and I have known several professional photographers to act in the same way. I always recommend that experience should be gained by exposing and developing a few plates on a few test subjects, and, as a golden rule, give plenty of exposure, which can be remedied in developing, whereas with a plate that has been under-exposed it is very difficult to obtain a passable result, although an expert may at times get a better result than a novice.

The Glass Plates.—Always use the best glass for small sizes, say up to 12 by 10. I use extra thick polished flatted crown. I find that some of this description now in the market is polished on one side only, which can easily be detected by passing the thumb-nail over its surface. The unpolished side feels pimply, which is very unsuitable for the film. A great many specks I have attributed to these pimples in the glass. On examining them under a microscope they appear to have a crater-like appearance, which acts as a receptacle for foreign matter, which becomes filled up and is detrimental to success, especially if the plate is kept for a few months. Patent plate is preferred by some. I object to it on account of its surface being so absorptive, and give the preference to the former. Great care must be taken to insure clean plates. I always soak them for a short time in dilute nitric or sulphuric acid—whichever is at hand—about one ounce to a pint of water. I never use washing soda or any alkali, as it attacks the surface of the plate, unless they are plates which have been varnished, and it is then almost indispensable. Should such be the case, only allow them to remain just long enough to have the desired effect—that is, to remove the varnished film. Remove them, and place them in clean water and stream singly under the tap, both sides, rubbing with the palm of the hand. After this treatment very little need be feared. Instead of polishing the plates, I prefer to use a substratum of albumen, as the labour is far less, and a better result is obtained. I always keep a good stock of prepared albumen on hand, which I prepare by the well-known formula of Mr. W. Ackland, which will keep for a year or two in good condition; it was published many years since.

To prepare the stock albumen I break each egg separately in a cup, and separate the yolk carefully, taking care to see that each egg is perfectly fresh and free from smell before adding to the whites of the other eggs already broken, as one bad one will spoil the whole batch. New-laid eggs are best on the score of freshness, but shop eggs I have found to answer the purpose very well. After the requisite quantity of albumen has been obtained, according to the quantity one requires to make, to every eight fluid

ounces of albumen mix together one ounce of water and twenty-four drops of glacial acetic acid, and add, pouring it into the albumen in a fine stream, and stirring constantly with a glass rod for one or two minutes. On no account is it to be beaten or whisked up, or the resulting preparation will have a milky appearance. It is then allowed to rest for one hour or more, and then strained through a piece of coarse muslin or cheese cloth. To this strained albumen is to be added one drachm of the strongest liquid ammonia, after which it is to be put up in bottles and tightly corked. I find it best to bottle it off in small bottles of about one ounce, or even half ounce, for when a bottle is once opened it requires to be used up. In this way any quantity can be made; it is then always at hand, and will keep for a very long time. It is the best system of preparing albumen that I know; I have used it ever since its publication. It is not only used as a substratum, but further on it will be seen that it plays a most important part in developing the plate. For use as a substratum use

Prepared stock albumen	1 ounce
Water	1 pint

Filter in the ordinary way through paper. Have all the plates ready in a dish of clean water, take one on a pneumatic holder kept for the express purpose (I find the red rubber ones the best, as they do not appear to get hard), stream under the tap, drain slightly, then flow over it from a clean glass measure a small quantity of the dilute albumen, which will drive the water before it; allow this to run off the plate, turn the plate round and pour the albumen solution at the end the first lot was poured off at, and return to the measure this time; the plate can now be set up on end to dry, or in a plate-rack, allowing the bottom corner only to rest on blotting or filtering paper. On a hot summer's day, this system of cleaning plates is not at all objectionable, and can be done more effectually than by polishing with the leather, &c. When the plates are thoroughly dry they can be edged with a solution of india-rubber dissolved in benzole, about six grains to the ounce, which is easily done by cutting a common camel's-hair brush to a stump, and tying on one side of it a strip of glass about a quarter of an inch wide, or a little less, allowing it to project down below the hairs about a quarter of an inch, which will act as a guide, and give an even edging all round without the slightest trouble. The plates can now be stored away in plate-boxes from the damp putting the prepared side all one way. They will keep good any length of time, or can be used at once.

In respect to the emulsion to be used, any good washed emulsion that will give a clean image can be used; it matters little whether it has been organified or not; it seems to make but very little difference. A simple bromized emulsion gives the best results; a bromo-iodized does not work so well unless the plates are prepared and used at once. I do not give here any formula for the emulsion, as so many forms have been published whose name is legion, and it will not serve any purpose to add to their number. Before I proceed to coat the plates, I prepare the preservative in quantity according to the number and size of the plates I intend to prepare.

Bitter ale	1 ounce
Pyrogallic acid	1 grain

Mild or sweet ale will not do, as it contains too much saccharine matter, which gives a very uneven coating, and is more readily affected by atmospheric changes. Sufficient of this preservative is poured out in a porcelain dish about half-an-inch deep; the plate is then taken on a pneumatic holder, and coated with emulsion in the usual way, and allowed to set, so that the last drop at the corner where the emulsion was poured off at is almost solid, and, without any intermediate washing, it is put at once in the preservative. Washing the plate *must* not be done on any account, or the desired result is not obtained, as I find it highly essential that the preservative must penetrate the

film, and not merely act as a varnish on its surface. If the plate has been washed, the film is so charged with the water that the preservative cannot enter, and it can only be accomplished by putting the plate in the preservative at once, so that as the solvents contained in the emulsion (ether and alcohol) leave the film the preservative enters and perfectly saturates it. I find also another great advantage in working in this way, and that is, one never need fear being troubled with drying marks; the plate can be taken up and examined without leaving any mark in the finished plates; not so if the plate has been washed. Although I mention the fact, it must not be supposed for a moment that I recommend the examination of the plates while drying. As a rule, the plates should not be moved until dry, and after removal they should be well dried before storing away, which can easily be accomplished by means of a flat hot water tin, sufficiently hot just to drive off the last traces of moisture. If plate-boxes are used for storing the plates, do not by any means use india-rubber cushions or pads; it does not matter how pure the rubber may be, for wherever the plate is in contact with it, an insensitive mark is produced. I generally put a strip of cardboard at the bottom of the box; I find it answers every purpose; also a piece at the top. It is best to have the boxes made of well seasoned wood. If the plates are packed up in packets, I find it convenient to pack them up in half dozens, using pieces of cardboard about two inches long, bent like an angle iron thus Γ , which are very easily and rapidly made by cutting a groove in a piece of hard wood with a saw. A piece of cardboard known as three-sheet board is cut to the required length, and about a quarter of an inch wide or a little more: one edge is inserted, and the part that projects is just turned over with the finger and rubbed down with some hard substance. The handle of a penknife answers the purpose admirably. The widest part lays over the end of the plate, and the narrowest over the edge of the plate. I have used this system for many years, and I find it answers admirably in every respect. The plates are then tied over with string, and wrapped up in one sheet of orange-coloured paper, one sheet of pitch paper (which can be bought at the shops where paper-hangings are sold, at one shilling per piece of twelve yards), and then in a final wrapper of brown paper, and pasted down. Plates packed in this way I have never found to take any harm on the score of packing.

The plates do not require backing unless the emulsion is used too thin. In preparing the plates it is best to have a good body in the emulsion, and, at the same time, it must not be so thick as to cause an uneven coarse film. I have kept plates prepared under this formula four or five months before exposure, and about the same time between exposure and development, and have developed them without either speck or stain.

The exposure of the plates depends upon circumstances, viz., subject, light, time of year, lens, stop, &c.; exposing a plate or so on a test subject is the best experience.

(To be continued.)

CHEAP HOME-MADE POCKET CAMERA, ETC.

BY RICHARD PARR.

IN the course of my experiments (described in some of your YEAR-BOOKS), I felt the want of a really portable "kit," that I could carry about with me without inconvenience; and as, after trying several, I found I could not buy what I wanted I went to work and made it as follows:—

I had an unusually good Darlot miniature portrait lens 1 inch aperture, $\frac{1}{4}$ inch back focus (equivalent focus about $2\frac{1}{2}$ inch), which I found to be very sharp over a circle two inches in diameter, and which, when used as the objective to a "sciopticon," enlarged the said circles fairly up to 12 inches,

which, for comparative purposes, was sufficient for my wants; and to this I built my "kit" thus. I laid in a stock of sheet brass, exactly 1-32nd inch thick, a little brass wire the same size, soft solder, and tools. To make the camera, I cut a strip of brass to form a tube $2\frac{1}{16}$ th inch inside diameter by $2\frac{1}{2}$ inch long (the lens projecting a little more than $\frac{1}{4}$ inch inside the camera), bent this into shape, and brazed it down the seam—soldering will do as well if done neatly. Fitted it on to a mandril of hard wood, and turned both ends quite true in the lathe; cut (with shears) a piece to fit the end for front. Cut out of this with a fret saw a hole truly central to fit lens mount, soldered it in its place, and the lens collar on to it in its place; soldered a ring of brass wire 1-16th inch thick round the outside of the camera at the back edge, to strengthen it. Got a piece of round brass 5-8th inch thick, bored a hole endwise in it, tapped (or screwed) it to fit a piece of 3-8th inch brass gas-tube, and, first putting lens in its place to see that focussing-screw came in a handy position, I soldered on bottom of camera, near the front, to form connection with stand, and polished it to my liking. Next I made, as before, a length of tube such size as when finished to fit stiffly inside camera, and putting it on a mandril in lathe, cut it into 3-16th inch lengths. Next made focussing-slide by getting a piece of brass plate exactly 3-32 inch thick, $2\frac{1}{2}$ inch by 2 inches, rounded the corners nicely, and soldered round one side, flush with the edge, a rim 3-16th inch deep. In the tray thus formed I fitted a piece of the 1-32 inch brass sheet, and through each corner put a screw tapped into the thick plate, and long enough to allow a piece of ground glass to lie between the plates. Next got the centre, marked a circle 2 inches diameter, and cut it out with a fret saw through both plates, and round the hole outside the thick plate soldered one of the 3-16th inch rings of tube, which, by slipping into camera, holds slide in its place, and polish off.

For the double dark slide I made two sides for each thus. Take two pieces $2\frac{1}{2}$ inch by $2\frac{1}{2}$ inch, and solder them together side by side, round the two longest edges and one of the short edges putting a piece of the 1-32 inch wire between them where you solder, to keep them apart just the thickness of the plate, and leave a space between them in which shall slide a plate of the same brass to form a shutter. Find the centre, and mark a circle 2 inches diameter, which cut out with fret saw as before, and solder one of the rings of tubing round it. Now to one of the "slides," solder on the opposite side to that where the ring is, and flush with the edge, a rim all round it $\frac{1}{4}$ inch deep; inside this, and leaving an equal space all round, solder another rim only 1-8th inch deep, and just large enough to take in a $2\frac{1}{2}$ by 2 inch plate (the size I am using). Now take the other "side" and solder on it, true with the edges, a rim $\frac{1}{4}$ inch deep, that will just fit easily all ways between the two rims, on the other side when placed together. Polish off clean, and place the two sides face to face in their proper position, and clamp them, and make a joint like a snuff-box hinge exactly up the centre line between them by soldering on a "joint" made with hollow "joint wire," 1-8 inch diameter, and wire to fit it. I prefer to make the hinge in three lengths, soldering on to one "side" a short piece at each end, and then fit a piece nicely in between, and solder it to the edge of the opposite side, first putting in the wire. Now, on opposite edge to the hinge, solder a brass spring catch, to fit without shake. Inside this slide and between the plates I use a blackened plate (cut a little less than the glass plates) with a small spring on the back to keep them well home in the slides; when well made and fitted, these slides are very compact, quite light-tight, and do not hold damp. The stand will require castings, for which I made patterns. The foundation is a clamp large enough to take in $1\frac{1}{2}$ inches, such as is used to screw domestic mincing-machines on to the edge of the table, with the screw, $\frac{3}{8}$ inch brass gas thread, and long enough to close clamp to $\frac{3}{4}$ inch, has a large milled head. On one side of the strengthening rib of clamp, and near the screw end, is cast a boss, to which screws a right-

angled bracket 1 inch long and wide in each leaf by $\frac{1}{4}$ inch thick; to this is screwed, hack to hack, another exactly the same; and to this last, back to back, another, with one leaf the same, and the other a boss, with a hole through it to let a piece of $\frac{3}{8}$ inch brass gas-pipe slide and turn in it. This boss is sawn through, and has an ear on each side or wing, which, by being pinched with a screw through the ears, closes the whole and fixes the pipe at any point. The end of this pipe is screwed to fit the socket on the bottom of camera.

The screws are all "capstan-headed," and turned by a small steel punch, which fits the holes in their heads. They are $\frac{3}{8}$ -inch thick, screwed gas-thread, and slip through one leaf of the brackets, and screw into the one under it. Each bracket turns on its screw, and, by this means, and the sliding pipe (4 inches long) give a universal adjustment, and the clamp will screw on a door gate, chair, or window in any position (I have frequently used it from a railway carriage window), and, if desired, the clamp can be unscrewed, and the brackets made to screw on the head of an ordinary tripod.

My intention was to make the brackets fit the top of an ordinary walking-stick fishing-rod, by making a top to slip in it, and fit such top with three small reels, with pinching screws, and on these reels have a few yards of copper wire with a kind of small tent peg at the end, so that by pegging these down and tightening the reels I could fix it anywhere, but I have not found it necessary so far.

The instantaneous shutter is made thus:—A brass tube ring to fit lens tube is soldered on the centre of a plate $1\frac{3}{4}$ by $1\frac{1}{2}$ -inch, with a flange turned down on the longest two sides $\frac{3}{8}$ -inch deep: the centre cut out with fret saw. Through the flanges at top and bottom are bored holes, and a shaft, $\frac{1}{2}$ inch or more thick, fitted in each, each shaft having a thicker portion projecting $\frac{3}{4}$ -inch on right hand side looking from camera, and having a milled head. To the top shaft is fitted and soldered the shutter (by bending it over), which has a piece of silk velvet (black) on its under side, stuck on with chromated gelatine cement, to make it shut well and exclude all light. The top shaft projects $\frac{3}{4}$ -inch on the left hand, and is fitted with a boss soldered on with a hole through it at right angles to shaft, and a set screw in the end going into the hole. A similar boss is soldered to the left hand side flange $1\frac{1}{2}$ -inch below top shaft, and a piece of india-rubber band threaded through the holes and tightened by the set screws, so that when shutter is opened the rubber wraps round top shaft and closes shutter when released quicker or slower according to its tension. For all ordinary exposures this is quick enough, but it is not so for my gelatine plates for good actinic light, so I added the following:—On top shaft, $\frac{3}{8}$ -inch inside the milled head, solder a piece of brass wire projecting half inch towards camera at right angles to shutter when closed, and curving upwards slightly. On bottom shaft solder a similar piece $\frac{3}{8}$ -inch long, with a loop on end. In this loop fasten a length of same wire by another loop like the links of a chain. Let this length of wire, or link, have a loop on top to slip on to projecting arm of top shaft, and its length be such that when bottom arm is perpendicular, it shall rest without pressure on top arm. Now, if all is right, a quick turn of bottom milled head towards camera—less than one quarter revolution—opens shutter, and when it is a little above the horizontal line, link slips off top arm and it closes. This is the quickest acting shutter I know of that is not automatic: As a matter of course, any size can be made in the same way according to lens, &c., it is intended to use.

I do not anticipate that many of our brethren are used to handling all the tools I am, but, as I am self-taught, and find it easy to dabble a bit in most of the arts and some of the sciences, I know there will be some who can, if they will; and if not, I trust my description is plain enough to be put into the hands of an ordinary workman with some hope of success, while, if it has any merit, it is that it is original, and has answered my purpose.

Correspondence.

CADETT'S PATENT SHUTTER—CRACKED NEGATIVE FILMS.

DEAR SIR,—In connection with Mr. W. Barry's very excellent modification—or, rather, improved method—of working the Cadett shutter, I would further suggest the desirability of reversing the angle of the pins or wires supporting the velvet disk, thus causing it to act silently and without raising dust, as otherwise would be the case by such a fan flapping up and down immediately in front of the exposed plate. It was only in this particular I preferred Cowan's "electric;" but now that it has been clearly shown how that admirable and "sweet" movement can be accomplished by "pneumatic" power, I consider the advantages decidedly in favour of the latter. One other modification I would also suggest, viz, instead of the top hole and wire arrangement to keep open the lid while focussing, just allow the ball to trail on the floor, and press on it with the foot, leaving the hands free to focus *ad libitum*. This plan will be found as efficient as it is simple, and dispenses with a deal of fine work requiring extreme caution to prevent light entering the front of the camera through the broad holes. Should this description not appear clear and sufficiently practical to you or any of your readers, I shall be most happy to furnish a drawing or drawings showing the actual working of these proposed modifications.

Cracked Negative Films—I discovered quite by accident one day, whilst preparing my negatives for retouching, that "there is nothing like rosin" for effectually and perfectly removing (as if by magic) the hair-like honeycomb cracks which occur so often at this season of the year in negatives coated with certain samples of varnish. Just dip the finger-end into a little of the impalpably fine powder, rub lightly over the cracks, and, Eureka! they are gone.—Very faithfully yours,
VINCENT HATCH.

Huddersfield, January 1st, 1879.

PHOTOGRAPHY BY MEANS OF OXALATE OF IRON.

SIR,—I fail to see what it matters to Captain Abney whether I write in the *Times* or not. The question at issue is, who produced the first photograph by oxalate of iron? And I re-assert that it was Dr. Phipson who did so in 1860, and that his process was published in 1861. Captain Abney confesses that he is ignorant of that publication, and yet he makes bold to assert that Professor Draper in America, in 1840 or 1843, or thereabouts (the exact date does not appear to be forthcoming), did something similar!

I happen to have been in Dr. Phipson's laboratory at the time that the first photograph in oxalate of iron was obtained, and I distinctly remember his showing me a capsule covered with green crystals of ferric oxalate, which, being exposed to the solar rays (one-half of the capsule being protected from the light for the sake of comparison), blackened like chloride of silver, and quite as rapidly. Shortly after this his process was published.

Just before writing my first letter on this subject I was shown the portrait produced on this occasion, and it is as perfect to-day, after a lapse of eighteen years, as it was the day of its production.

There is a great difference between the use of oxalate of iron as a photometer, and its use as a photographic agent for obtaining pictures.

A little later, in 1863, Dr. Phipson made known a new method of measuring the chemical action of daylight by means of molybdic acid—a most simple and accurate process of volumetric analysis—but he would never have

thought of obtaining pictures by the same process. Very probably Sir John Herschel was acquainted with the sensitive nature of ferric oxalate; but, much as he has done for photography, Sir John never published a process for obtaining a photographic picture by means of oxalate of iron. In Dr. Phipson's photograph the image was in oxide of iron; in that of Dr. Reynolds it was in silver deposited on the oxalic image; in Mr. Willis's ingenious process it is in platinum deposited on the same.

In conclusion, allow me to observe that the volume of Professor Draper's memoir referring to oxalate of iron as "an excellent photographic substance," quoted by Captain Abney, was only published a few months ago, and that, to establish any claim to priority, such a quotation is of no value whatever. In matters of science it is customary to quote original papers only, and the date of publication. I have too much respect for Captain Abney's opinion in these matters to allow this oversight of his to pass unnoticed.—I am, sir, your obedient servant,
 London, Jan. 4th, 1879.

THE LUXOGRAPH TESTIMONIAL.

DEAR SIR,—Business is our motto, not controversy. The very liberal offer of Mr. Faulkner is a misstatement, for his offer was for the complete apparatus as patented, and the £15 would not nearly cover the actual cost of production.

We are glad of this opportunity to confirm the statement of Mr. Gregson that Mr. Faulkner did express his enthusiastic and eulogistic opinion about the Luxograph, or, as Mr. Gregson so aptly put it, "he (Mr. Faulkner) expressed his admiration, and that in no unmistakable terms, either"; so much so as to induce Mr. Gregson and Signor Lombardi to become purchasers.—Yours truly,
 36, Strand, W.C., January 2nd. ALDER AND CLARKE.

PHOTOGRAPHIC CONSERVATISM.

SIR,—It has been fully impressed upon my mind for some time past that photographers are as a class far too conservative in their ideas and practices, even where their own interests are most deeply concerned.

A convincing proof of the truth of this may, I think, be found in the fact that although so much has been written of late in praise of emulsion photography, and of the advantages which may be secured by using dry plates in the studio for ordinary portraiture, how few there are to be found who have availed themselves of this new power.

I know from past experience, both personal and relative, that there is a deep-seated prejudice existing in the minds of professional photographers against the introduction of dry plates for portraits in the studio, so contrary, say they, to long-continued usage—such an entire change in the method of working. But what illogical conservatism does this appear when we consider how very much more widely the field of operations may be extended by their adoption!

I firmly believe that the time is not very far distant when the present system of taking negatives by the wet process will be entirely superseded by the dry, and I can easily imagine that the former will one day occupy a place in our memory analogous to that of the old tinder-box, by means of which we used in times of yore to obtain our light, and the vessel which now contains our silver solution will be thrust aside into lumberdom, and be hereafter shown to our successors as curiosities of the elementary period. But, after all, I am not one who would treat such a good old servant as the nitrate bath has undoubtedly been with ignominy and shame; it has been a much-abused, and even more often ill-used friend, frequently worked beyond its power of endurance, and when the last straw has been piled on, and fairly broken it down, how often have we heard the remark, from its merciless oppressor, "Why, what on earth is the matter with my bath? I am sure I have done nothing to it." Well might the reply

have been given, in gasping tones: "Nothing—nothing—nothing; therefore it is that I can do nothing more for you."

Let us, then, during its few remaining days treat the old bath with respect, and when the time of its dissolution shall have come, taking care to obtain all its little remaining siller first, bury it decently with full photographic honours.

WILLIAM COBB.

Woolwich.

THE PRIZE INSTANTANEOUS SEASCAPES.

SIR,—Pity a poor medallist! The jury at the late Photographic Exhibition at Pall Mall East have inflicted upon me a medal. Not that it is any novelty for me to receive such a distinction, but in this case Col. Wortley says I ought not to receive it, and "Is he not an honorable man?" So you will see I am extremely unhappy. Had I only have been content to produce "nocturnes" in black and white, or "arrangements" of sky, water, and moonshine, as perpetrated by my gallant rival, history showeth that I should not have been troubled with the above mentioned distinction.

My opponent is certainly powerful: "he can call up spirits from the vasty deep," although they do not always seem to come. He is continually invoking the aid of the London Photographic Society. Does he wish the members of the Council who acted as jurors to acknowledge their incapacity as judges? or does he wish that in matters of seascapes the award be left to the tender mercies of Col. Stuart Wortley, this redoubtable son of Mars to be at once President, Council, and Dictator? This gentleman, as Napoleon said of our Peninsular heroes, "does not know when he is beaten." I would, however, recommend for his guidance in future (whether he be holding an argument or making photographs) the maxim, "*Rien n'est beau que le vrai.*" (There is nothing so lovely as truth).—Yours truly, PAYNE JENNINGS.

[As this correspondence can no longer tend to edification it must close here.—ED.]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The first meeting of this Society for the present year took place on Thursday, January 2nd, in the large room of the Society of Arts, Adelphi, EDWIN COCKING, Vice-President, in the chair.

The Hon. Sec. (H. Garrett Cocking) read the minutes of the annual meeting, which were confirmed.

The evening, as on previous nights, was devoted to a lantern exhibition, when to a crowded assembly a large number of Mr. F. York's views in Paris and the Paris Exhibition were exhibited by Mr. York, Jun., Mr. McCall reading explanatory notes respecting the same. Some slides produced by Messrs. Payne Jennings and Mr. M. Ayres were also exhibited.

Votes of thanks having been passed to Mr. F. York, Mr. York, Jun., and Mr. McCall, it was then announced that at the next meeting, in February, Mr. T. Hasard would read a paper on "Gelatine Plates in the Studio," and Mr. W. Willis, Jun., would give a demonstration of his new Platinum Process, and the proceedings terminated.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of this Society was held on Monday, the 6th inst. (the correct day, New Year's Day, being inconvenient), at the usual place of meeting, the Museum, Queen's Road,—Mr. F. DAVEY in the chair.

The minutes having been read and confirmed, Mr. H. T. Stevens was unanimously elected a member of the Council in the room of Mr. Holt, resigned.

In the absence of the President, Mr. W. W. STODDART, the Hon. Secretary, then read a most interesting and valuable paper by that gentleman, entitled "Notes on the Action of Light," (see page 14), which was listened to with much pleasure.

Mr. H. A. H. DANIEL remarked that the paper bore out a remark or two to which expression had been given by the Presi-

dent on a former occasion, and which he knew was the result of a rather strong belief held by that gentleman.

Mr. E. BRIGHTMAN thought that Mr. Stoddart was a little wrong in assuming that the change which possibly took place in chemicals by exposure to light was necessarily detrimental to photography; for instance, in the case of the nitrate bath it was the reverse.

Mr. T. DAVEY thought that where operators constantly got uniformly good results when working with such chemicals the idea was to a great extent negatived.

Mr. BRIGHTMAN stated that some time since he had tried a few experiments, and his experience was that the light had not had a detrimental effect on the chemicals photographically.

Mr. DANIEL observed that whatever the opinions were, it formed a subject in which it would be very well worth making some careful experiments, and the results of which would be interesting.

Mr. BRIGHTMAN proposed, and Mr. DANIEL seconded, a cordial vote of thanks to the President for his interesting paper. The latter gentleman, in doing so, said all must feel that Mr. Stoddart did not prepare a paper for them without a great deal of trouble, in consequence of his engagements being so very numerous, and therefore he knew the resolution would be most heartily carried.

Mr. DANIEL moved the following resolution, which was put to the meeting and carried unanimously:—"That this Association desires to express its regret at Mr. J. Traill Taylor having relinquished the editorship of the *British Journal of Photography*, and sincerely wishes him every happiness and prosperity in the future."

After the introduction by Mr. Davey, of a short discussion on the subject of nitrate bath-holders, which was continued for a short time, the meeting was adjourned.

Talk in the Studio.

TESTIMONIAL TO MR. TAYLOR.—A goodly assemblage of photographers dined together at the Café Royale, last Saturday evening, under the presidency of Mr. Glaisher, to bid farewell to Mr. J. T. Taylor, and to present to him a token of good-will in the shape of a handsome gold chronometer, and a purse of gold, which were handed in an appropriate speech by the chairman, and duly acknowledged. Various other speeches filled up a pleasant evening. The vice-chairs were filled by Mr. Walter Bird and Mr. A. L. Henderson.

LARGE PHOTOGRAPHS.—At a recent meeting of the Berlin Association for the Promotion of Photography, among other specimens of photography exhibited, were some remarkable landscape pictures by Herr Holtermann, of Sydney, Australia. These are more especially distinguished for their size; they are mounted on an endless band of paper strengthened with linen, nearly 100 feet long. Two colossal panoramas of Sydney and Melbourne have been each made from about a dozen sheets, 18 by 20 inches, very skillfully joined; the separate parts harmonize very completely in drawing, tone, and depth. The last on the list was a picture which, as could be easily seen, had been printed from a single negative, and its size, 150 by 93 centimetres, showed it to be quite an uncommon photographic feat.

STABBING A PHOTOGRAPHER.—At the Thames Police Court Capoo Basso, an Italian seaman, was brought before Mr. Saunders charged with unlawfully and maliciously cutting and wounding John Cass, a photographer, of 1, Wellelose Square, St. George's. Late on Saturday night the prosecutor was standing at the door of 1, Beezes Hill, Shadwell, talking to a young woman, when the prisoner came deliberately up to him, and, without uttering a word, struck him a sharp blow on the neck just below one of his ears, and then ran off at full speed. The prosecutor was not at first aware he had been stabbed, but, feeling a stinging pain, he put his hand to the place, and on withdrawing it found it covered with blood. He and his nephew, Andrew Gough, ran after the prisoner, and his nephew captured him in Causton Street Road, and gave him into custody. At Leaman Street Station the prisoner was searched, and a pocket knife was found upon him the blade of which had marks of fresh blood upon it. A divisional surgeon of police was immediately sent for, who dressed the wound on the prosecutor's neck. The evidence having been interpreted to the prisoner by a fellow-countryman, he said he was drunk on Saturday night, and got knocked about by some persons; but he had no recollection of stabbing the prosecutor. In answer to the magistrate

the witness said the prisoner ran too swiftly and straight to be intoxicated. Mr. Saunders committed him for trial.

AN INSOLUBLE CEMENT.—A very valuable cement has been discovered by Mr. A. C. Fox, of which details are published in *Dingler's Polytechnisches Journal*. It consists of a chromium preparation and isinglass, and forms a solid cement, which is not only insoluble in hot and cold water, but even in steam, while neither acids nor alkalis have any action upon it. The chromium preparation and the isinglass or gelatine do not come into contact until the moment the cement is desired, and when applied to adhesive envelopes, for which the author holds it to be especially adapted, the one material is put on the envelope covered by the flap (and therefore not touched by the tongue), while the isinglass, dissolved in acetic acid, is applied under the flap. The chromium preparation is made by dissolving crystallized chromic acid in water. You take: crystallized chromic acid, 2.5 grammes; water, 15 grammes; ammonia, 15 grammes. To this solution about 10 drops of sulphuric acid are added, and finally 30 grammes of sulphate of ammonia and 4 grammes of fine white paper. In the case of envelopes, this is applied to that portion lying under the flap, while a solution prepared by dissolving isinglass in dilute acetic acid (1 part acid to 7 parts water) is applied to the flap of the envelope. The latter is moistened, and then is pressed down upon the chromic preparation, when the two unite, forming, as we have said, a firm and insoluble cement.

To Correspondents.

SILVER.—We do not know of any special house in Paris to which we can recommend you for goods. But in asking details of anything previously mentioned in the NEWS, you should make specific reference, as we cannot tell from an indefinite allusion to what you refer to. 2. We have published all details of Mr. Willis's platinum process which have been made public. For any further details application should be made to Mr. Willis, or the Albion Albumenizing Company, who some time ago were advertised as agents.

B. R. S.—The convex surface given to some portraits is produced by means of a press made for the purpose. The mode of producing the glazed or enamelled surface we have often described. A piece of plate glass is thoroughly well cleaned, then coated with a tough plain collodion. When dry, it is coated with gelatine. Upon this the print is placed face downward, and when dry removed from the glass, bringing away gelatine and collodion, and so acquiring the glazed surface desired. We cannot in this column enter into full details.

R. M.—Your printing bath has doubtless become too weak for use. The mottled poor print of which you complain indicates this. You should remember that every piece of albumenized paper floated on the solution abstracts silver from the bath, hence it requires refreshing with stronger solution to make good the deficiency in silver as well as in quantity.

YOUNG AMATEUR.—Your question, "Is it possible to take portraits in an ordinary sitting room?" is rather indefinite, inasmuch as everything depends upon the size and position of the windows. As a rule, it is not possible to take good portraits so; if it were, there would be no necessity to build special studios; but we have seen good portrait negatives produced in a sitting room with large bay-window. In fine weather good portraits may be secured in the open air.

W. J. ANCKORN.—We shall be much pleased to see one of the specimens to which you refer, and to receive details for our readers.

B. G.—The terms "strong" and "weak" are too indefinite except when used by experienced people speaking to experienced people. An experienced photographer knows, for instance, that in speaking of a printing bath, one of 20 grains to the ounce is weak; whilst one containing more than 50 grains to the ounce is strong; whilst a negative bath would be weak at 25 grains and strong at 40 grains. It is wise at all times to be definite. For your purpose a printing bath of from 40 to 50 grains per ounce will answer well.

A STUDENT.—The subscription to the Photographic Society of Great Britain is one guinea annually, and one guinea entrance fee. To the South London Society the subscription is half a guinea annually. To secure admission into either, you must be proposed by a member, and you will then be duly submitted to the ballot, and doubtless elected.

YOUNGSTER.—Your transparency arrived broken; but there is sufficient to show the fault of which you complain. The fault is due partly to over-exposure, but more to over-development. Remember that a transparency requires development different from that required by a negative, much shorter application of the developer being needed. You will get rid of the grey tone by toning with a neutral solution of chloride of gold.

SIGNOR LOMBARDI and several other correspondents, arriving late, are compelled to stand over until next week.

The Photographic News, January 17, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. PHOTOGRAPHY AT THE STAFF COLLEGE, SANDHURST—THE LIQUEFIER OF OXYGEN—HOW TO TELL GOOD GELATINE FROM BAD.

Photography at the Staff College, Sandhurst.—Instruction in photography is becoming quite a feature in the technical education of staff officers. At Chatham, as our readers know very well, there has been for many years past a school for the instruction of officers and non-commissioned officers of the Royal Engineers in camera work and printing, the late instructor being Captain Abney, R.E., F.R.S., while the present one is Lieutenant Darwin, honorary secretary of the Photographic Society of Great Britain. Photography is one of the many arts which Engineers are called upon to practise with an army in the field, in the same way as they undertake surveying, telegraphy, lithography, &c., and it forms part of their ordinary duties; but in the case of officers in the Staff College the matter is different. The Staff College is for the purpose of training army officers, to fit them to take up staff appointments, which carry extra pay, besides giving ambitious young soldiers more prominence than they otherwise enjoy in their regiments. If a lieutenant or captain desires staff employment, he must go through a two years' course of study at Sandhurst College to qualify himself, and to get into the College it is necessary to pass among the first in a competitive examination. Thus it is no easy matter to secure a place on the staff. At the College the curriculum includes ordinary subjects, and extra subjects; in the former the students must qualify in order to pass out, in the latter they pass for honours or for special mention. Geology, telegraphy, and photography are special subjects, and of all, it is photography, apparently, that is the favourite. The Professor of Chemistry at Sandhurst College, Dr. E. Atkinson, F.C.S., is at the same time instructor of photography, and he finds his students so alive to the theory and practice of the art, that he has of necessity to bring before them all modifications and improvements in the dry and wet processes as they arise. The number of students who take up photography has of late much increased, and in the list which has just appeared of qualified staff officers, a large number have made themselves familiar with the camera during their sojourn at Sandhurst. Thus, to quote from the official list, we have Lieutenant Watson, 1st Dragoon Guards, "very good in telegraphy, photography;" Captain Fox, R.A., "very good in photography;" Captain Bell, V.C., R.E. (an Ashantee officer), "special mention in photography;" Captain Paterson, 16th Foot, "very good in photography;" Lieutenant Morgan, R.M., "good in photography;" Lieutenant Carey, 98th Foot, "good in photography;" and Captain Miles, 101st Fusiliers, "good in telegraphy and photography." Seven officers, therefore, who have passed for staff appointments this year, are qualified photographers, and capable of affording aid to a general in the field by reconnoitring with the camera, or illustrating his reports with photographs. It would be well if officers of the navy were similarly instructed; but we believe that so far the Royal Naval College at Greenwich has taken no steps to secure for their students any special instruction of the same kind.

The Liquefier of Oxygen.—Our readers will be glad to learn that M. Raoul Pictet, the liquefier of oxygen, who for some months past has been in a critical state, is now restored to health. M. Pictet, whose arduous researches, it may be remembered, were crowned with success about twelve months ago, suffered very severely from his work, and both brain and eye-sight were materially impaired. Not only were the experiments of a very dangerous character, involving, as they did, the exertion of enormous pressure, together with a very low temperature—for it is

only under these conditions that the gas can be liquefied—but the strain upon the mind of the investigator, who knew that others were upon his track, was for a time exceedingly great. M. Cailletet, of Paris, who at the same time, or immediately afterwards, completed the task by liquefying hydrogen and nitrogen, was also prostrated by his labours, so that there cannot be a doubt as to the hard work that was involved in these investigations. M. Raoul Pictet, as we have said, is now restored to perfect health, and will be in a position to enjoy the honours recently bestowed upon him. Besides the medal from our Royal Society, to which we have already referred in these columns, M. Pictet has had conferred upon him the honorary degree of doctor, by the University of Geneva—his native town—while the French Government, not to be behindhand, has made him a Chevalier of the Legion of Honour.

How to tell Good Gelatine from Bad.—Dr. J. M. Eder, whose scientific researches into the question of developers will still be remembered by our readers, is now adding to our obligations by publishing some results upon an investigation of gelatine. If there is a material more than any other among a photographer's requisites of which he knows comparatively little, it is gelatine, and it is this fact more than any other, we are convinced, which has hitherto stood in the way of the general adoption of carbon printing. Chemists are unable to tell us much about the material, and the consequence is, we have to rely pretty much upon what manufacturers choose to supply us with. It stands to reason that bone-gelatine must differ materially from skin-gelatine, while the product of one animal may not be the same as that from another. Some gelatines—the inferior ones—dissolve at a low temperature, and others, again, set with extreme difficulty. "It should be observed," says Dr. Eder, "that good gelatine, when dissolved, not only colours water very slightly, but gives an almost colourless jelly." Dr. Eder suggests two practical ways of ascertaining the quality of gelatine, which our readers would do well to bear in mind. The first is—although it may not hold good throughout—to see how much water the material is capable of absorbing, the more water taken up the better being the gelatine. To find out this, a piece of gelatine should be accurately weighed, and then permitted to soak for twenty-four hours in water at 15° Centigrade. The examination of a series of samples in this way will soon teach something about them. Another test is to find out the weight necessary to crush a gelatine jelly. Thus if you have half-a-dozen samples to examine, solutions are in the first place prepared, five grammes of gelatine being dissolved in forty-five cubic centimetres of water. Half-a-dozen beakers, or glass vessels of precisely the same diameter, are obtained, and the solutions placed therein to set at a temperature of 15° C. All gelatines should set at this temperature; if they do not, says Dr. Eder, they may be put on one side as unfit for photographic use. When set, there is lowered upon each jelly a little apparatus consisting of a piece of tin shaped like a watch glass, to the centre of which a wire is attached. The convex face touches the gelatine, and when it is weighted sufficiently it breaks through. At the upper end of the wire is a funnel, and to weight the apparatus small shot is dropped into the funnel. The weight of the apparatus should, of course, be in all cases the same, and this equality is soon brought about by adding shot to make up weight. The jelly which proves to be the firmest may be regarded as the best gelatine. An arrangement for steadying the wire is necessary, and this may be effected by covering the mouth of the beaker with a metal plate having an orifice through which the wire passes. The moulded metal plate touching the gelatine need not be more than 1.15 centimetres in diameter, while such is the toughness of the gelatine in some cases, that three pounds of shot are occasionally necessary before the apparatus tears the film. The

ougher the gelatine, we need hardly say, the better it is. The better kinds of gelatine are all found to dissolve pretty well at the same temperature, but in the case of gelatine of inferior quality, this dissolves in water at a very low temperature.

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

ACCORDING to what has been stated, a Nelson's gelatine, which is especially recommended for collotypes, is not so well adapted for the purpose as most of the others. The fact is remarkable, but the author is unwilling to believe that his method of testing is in fault; on the contrary, he is strongly of opinion that this gelatine is inferior for collotyping purposes to many of the German and French gelatines enumerated in the table. To prove this assertion he submitted two collotype plates, one prepared with Nelson's gelatine, the other with a French gelatine (No. 10), to excessive pressure by repeated pulls in a printing press; the French gelatine was still sound when that of Nelson was completely crushed.

The secret of success in the collotype process, as in that of chromate photography generally, lies in the proper selection of a good gelatine. Nevertheless, nowhere is less care taken than at this stage, and the natural consequence is not long in making its appearance. Before employing gelatine for photographic purposes it is of prime importance to test it thoroughly; by so doing a whole heap of failures will be avoided.

One question still remains to be answered: Are gelatines rich in gluten or those rich in chondrin the best? Which of these is best adapted for collotyping, and which for carbon printing? To ascertain the amount of chondrin contained in a specimen of gelatine the author tested it with alum. For this purpose it is necessary to have a solution of a standard degree of concentration—10 per cent.—for if it be more highly concentrated nearly every kind of gelatine will set, in consequence of a certain amount of chondrin which is always present, whereas if it be more largely diluted the reaction will fail to appear. Of all kinds of gelatine those manufactured by Nelson are the richest in chondrin. In a tolerably dilute even strongly-heated solution of Nelson's gelatine both alum and chrome-alum produce an immediate precipitate. As regards the proportion of chondrin contained in them, Nos. 10 and 11 come nearest to those of Nelson, while the other kinds may be reckoned amongst those rich in gluten. The difference is best observed when the tests are undertaken simultaneously.

Chondrinous and glutinous gelatines do not behave alike in chromate photography. If plates be prepared in precisely the same way with a gelatine of each kind, and exposed under a negative, the one containing the larger amount of chondrin will become insoluble in a manifestly shorter time than the other. Glutinous gelatines develop with greater facility in hot water; but chondrinous gelatines become insoluble more rapidly. The author considers the gelatines that are rich in chondrin to be especially adapted for collotype; they are made more completely insoluble by the action of chromium oxide than those which are rich in gluten. It must be understood, however, that the latter may become equally insoluble under a longer exposure. He is also of opinion that chondrin produces prints of greater brilliancy, and with sharper contrasts. Gelatines which he proved to contain a larger amount of chondrin are excellent kinds for collotyping; those which are rich in gluten are better adapted for carbon printing. It should also be noticed that Nelson's gelatine No. 1 is not sufficiently soluble for the carbon process, for which purpose French gelatines are to be

preferred. For the collotype process, however, it should not be forgotten that the gelatine must be capable of withstanding a high degree of mechanical pressure—this is the first condition; that it should be rich in chondrin is only of secondary importance.

In corroboration of this opinion the author cites the testimony of one of the most celebrated workers with the collotype process in Germany, who, in a private communication, informs him that for the preparation of his gelatine he always uses the refuse of calves' heads. Now, it is well known that the members of all young animals which are still in process of development are rich in chondrin. This, however, is contrary to the opinion of Husnik, who states in his work "Gesamgebiet des Lichtdrucks," page 57, that the skins and sinews of fully formed animals make better gelatine for collotyping than those of young ones.

Boiling for a long time continuously renders gelatine quite useless, more especially for the collotype process. It has consistency, and consequently its carrying power, as may be easily seen, by submitting it to the test for this purpose above described.

The author has not been able to discover an accurate method of analysing gelatine quantitatively for chondrin; he gives, therefore, the reaction with alum as an approximate determination. By adding chrome-alum we increase the carrying power of gelatine in the same proportion as its hardness; but letting it stand for half an hour is sufficient to equalize this difference. Gelatine mixed with chrome-alum is able to bear only one-fourth of the weight that it could previously support; the number thus formed, however, stands in no kind of relation to the amount of chondrin contained in the gelatine, but depends rather on its carrying power.

PHOTOGRAPHIC ENGRAVING.

BY CAPT. J. WATERHOUSE, B.S.C.*

Geymet's Method.—The fourth method, that of electrotyping from a gelatine relief obtained by the pigment-printing process, is somewhat similar in principle to Placet's process, but as there are important differences, and the process appears likely to prove of some utility, it may well be treated separately.

According to M. Geymet, who has very fully described the process and all the manipulations of preparing and electrotyping the reliefs in his "Gravure Heliographique," it was the invention of M. Audra, a French amateur.

Pigmented gelatine tissue is sensitised and exposed to light exactly in the manner described for the Autotype process. It is transferred to a smooth glass or a polished copper plate, developed in warm water, and when dry is metallised and electrotyped. If the subject is one in line or dot only, the above operations are sufficient; but if the subject is a photograph from nature, or any other with gradation of shade, it is necessary to obtain a grain, and this M. Geymet does by taking a copperplate with its surface grained or engraved with a ruled or roulette tint, inking it up in the ordinary way, and covering it with a coating of transfer collodion. When dry the film of collodion is stripped off the plate, and carries with it the impression of the grain. This film is then placed between the cliché and the sensitive gelatine film, and serves to break up the shadows in the more transparent parts of the cliché.

A similar process has been used at the Depot de la Guerre, in Belgium, for the reproduction of maps.*

Last year, whilst making some experiments on this process, I succeeded in obtaining the necessary grain by chemical means which produce a finer and less artificial effect, and I have also made a few other modifications in the process, which may be worth recording at length.

* Continued from p. 17.

* See Maes and Hannot *Traité de Topographie*, &c., p. 330.

* Continued from page 19.

A piece of the ordinary autotype tissue is sensitized in a 5 per cent. solution of bichromate of potash. When dry, it is exposed to light under a reversed negative, and then transferred in cold water to the surface of a well polished copper plate, and squeezed down into close contact with it. In order to prevent subsequent adherence to the newly deposited copper in the electrotyping bath, the copper plate is silvered by rubbing it with a little of the following solution mixed with tripoli.

Nitrate of silver	1 part
Cyanide of potassium	10 parts
Water	100 "

The gelatine tissue attached to the copper plate is allowed to dry, and then developed in warm water in the usual manner, great care being taken not to loosen the lines, an accident which is very liable to happen, though the preliminary drying of the tissue before developing tends to prevent it.

When the image is quite clear from all soluble gelatine, the plate is well drained and plunged into a bath containing—

Tannin	5 parts
Strong spirits-of-wine	100 "

This at once removes all moisture from the gelatine relief, hardens it, and gives it a fine grain, coarser in the shadows than in the lights. The plate remains a few minutes in this bath till the action is complete in the deepest shadows; the tannin is then washed off with a little spirits-of-wine, and the plate is allowed to dry.

The gelatine relief has now to be prepared for receiving the electrotype deposit. A band of copper having been soldered to it, the back of the plate is coated with Brunswick black, to prevent deposition of the copper upon it. When the backing is dry, the margins of the picture are cleaned with a little of the silvering solution. The gelatine surface then receives a very slight coating of wax dissolved in turpentine, which is well polished off, and is rubbed over with fine plumbago or silver-bronze powder to render the surface conducting. The plate is then ready to be placed in the depositing bath.

Any good electrotyping arrangement may be used, but I prefer a Smee's battery with a separate depositing trough containing a solution of 10 parts each of sulphate of copper and sulphuric acid in 100 parts of water.

A plate of copper, to serve as an anode, and connected with the silver plate of the battery, is laid horizontally about an inch above the bottom of the depositing trough, which should be large enough to allow the plate bearing the gelatine relief to be slipped under the anode. The relief-plate is connected with the zinc plates of the battery, and, when everything else is ready, the circuit is completed by slipping it into the depositing trough under the anode.

By laying the plates horizontally in this manner the deposit is more even, and the gelatine film seems to be more readily covered with copper.

When the deposit of copper is of sufficient thickness it is separated from the matrix, and only requires a gentle oil-rubbing to be fit for printing.

The plates obtained by this method show very good half-tone, with an almost imperceptible grain, giving the effect of a fine chalk-drawing.

I have lately tried to obtain the images upon the copper by the double transfer process, making use of a flexible temporary support, consisting of paper coated with india-rubber, as first proposed by Swan, which can easily be removed with benzole after the transfer of the gelatine image to the copper. The grain is given to the image by soaking it in water after the removal of the india-rubber paper, and then applying the solution of tannin in alcohol. This plan seems likely to be successful; if so, it will greatly simplify the operations, and enable engraved plates to be obtained from any ordinary negative without the trouble of reversing.

By electrotyping direct from the gelatine relief, the results are always rather heavier and coarser than they should be, because, although hardened and insoluble, the gelatine relief can always absorb a little of the copper solution in the depositing trough, and consequently the image swells and loses sharpness.

The strong tanning given to the gelatine film, and the preliminary coating of wax before metallising the surface, obviate this defect to a considerable extent; but it may perhaps be better to obtain a matrix in lead by pressure from the gelatine relief, and then to obtain the printing plate by electrotyping twice from the lead matrix. This is a more round-about and expensive method, but is likely to yield finer results, and has been adopted by Woodbury and Rousselon in the processes next to be considered.

The process is simple, and if it could be successfully worked out it might be usefully employed in this country in reproducing shaded maps and for other miscellaneous purposes. It has the very great advantage over photocolotype that the plates can be corrected, if necessary, and can be printed in any numbers in the ordinary copper-plate press without risk of breakage or damage to the printing surface

COLLODIO-BROMIDE EMULSION PLATES.

BY WILLIAM BROOKS.*

Development.—After the plate has been exposed, take it on a pneumatic holder, and flow over it equal parts of alcohol and water. I must here add a caution not to use the alcohol too strong, or it will attack the film unevenly and cause mottling, especially in the high lights, as I am sure, from past experience, this is one of the causes. It is not seen so much in the half-tone, and scarcely at all in masses of foliage, or where the subject is well broken up. If mottling does occur, it is mostly at the thick end of the plate. I do not know if this corresponds with the experience of other workers. If the alcohol is used without diluting (say at a s.g. of .825) the mottled markings are very large, and as the alcohol is diluted with water they become smaller and smaller till they disappear altogether. I generally allow it to soak well into the film for about two minutes, of the strength mentioned above (half water and half alcohol). Methylated spirit answers every purpose, providing that it is free from gum (if contaminated with gum, it turns milky on the addition of water). If a quantity of plates are to be developed, I prefer to immerse each plate in a tray containing the spirit, as it is then done effectually. The plate is then taken and allowed to soak in a dish of clean water, and rocked about until the water flows evenly over its surface. Previous to applying the developer, flood the plate with the following—

Stock albumen (as above)...	1 part
Water	4 parts

Allow this to soak well into the film; well rock the plate to ensure even action; not less than one minute must be allowed for this part of the operation. The plate is then slightly drained, and the alkaline developer applied, made from the following stock solutions—

P.—Pyrogallic acid (best)	96 grains
Absolute alcohol	1 ounce
A.—Sat. sol. carb. ammonia	4 ounces
Bromide of potassium	2 drachms
Water	8 ounces

A few drops of solution P for 9 by 7 plate (say five drops), and one ounce of solution A, are mixed in a perfectly clean measure, and at once poured over the plate; as soon as it is covered it must be rocked vigorously for a few seconds, so as to make it blend with the albumen on the plate, and if the plate has been properly exposed,

* Continued from page 21.

it will at once make its appearance, gradually acquiring intensity.

After the developer has been on for some little time, should it apparently cease in its action, drain it off, and again apply a little of the prepared albumen solution for about half a minute; drain again, and apply the alkaline developer as before; the image will then, perhaps, rush out very rapidly. This method can be repeated as often as necessary; but, as a rule, with a properly exposed plate, one application of the albumen is sufficient. If more density is required, a drop or two more of P solution can be added. If too much pyro is used, a very hard negative is the result, so it must be used with judgment. I have actually developed a 24 by 18 plate to full printing density with only half a grain of pyro. I think I mentioned the same fact in one of my papers read last year before the South London Photographic Society. I see that Mr. Henry Cooper refers to pyro being used with caution. The formula given for solution A is given for work under normal conditions. In the winter time the bromide can be reduced one-half, and in very warm weather it can be increased.

I have used the albumen as given above for several years, and the more I use it the more I like it, as it gives an image so much like a good wet plate taken under the best conditions.

Should it be desirable, the intensity can be brought up in the ordinary way before fixing with acid pyro and silver, same as for wet plates. The plate must be well washed to free it from all traces of ammonia, and before the silver is added to the acid pyro it is first applied to the plate alone, which will generally be sufficient to neutralize whatever may have remained in the pores of the film. The plate is then fixed in the ordinary way with—

Hypo	2 ounces
Water	1 pint

and then well washed.

I also, whenever I use hypo for fixing, especially for those films which are very porous, allow the plate to soak in plenty of water for half-an-hour to get rid of all traces of hypo. The plates require to be dried spontaneously, and then varnished in the usual way.

By the above system last year I prepared for two friends of mine 156 plates which were exposed on the Continent, and returned to me to develop, and I developed 154 good negatives; the other two were faulty, through one being exposed twice, and the other not at all. Some of the negatives were perfect gems.

I think plates prepared and developed in this way would meet all the requirements for the Paget competition, which, I believe, is to be held this year.

GOOD PRICES V. HARD TIMES.

BY G. FRANK E. PEARSALL.*

HAVING had various opportunities of observing the result of different experiments how to keep up business in these hard times, and having given considerable thought to the important subject whether it is advisable or necessary to reduce the price of pictures, I propose to relate my observations, feeling that a discussion on so vital a question once started, will induce others more able than myself to give the profession their views.

1st. The question occurs, Is it wise to lower the price of photographs, when in all probability the cost of producing them must continue to increase in the same ratio as in the past? For it must be admitted that the motive power instrumental in bringing photographs up to their present state of excellence has been chiefly by the increased cost of producing them. Therefore it is not reasonable to expect the same for the future development of our art, which, notwithstanding the rapid strides it has made, is still in its

infancy, and must attain a greater perfection in the future. Thus, with but a moment's reflection, it does not appear that it would be either wise or advantageous to lower the selling prices of photographs; but, on the contrary, such a course must be productive of harm to the profession, lowering its moral standard, and impeding further progress in artistic improvement. To make better work for a small than one would for a large price is hardly a human attribute; therefore to reduce the prices necessitates and is but a reduction of wages, which is certain to dull ambition's keenest monitor.

2nd. The question is asked, Is not the public to be considered; have they no rights that we photographers are bound to respect? They say they cannot afford to pay as much as they used to. I say, most emphatically, we are respecting your rights; we are aware the times are hard, that money has a greater purchasing power than formerly, but we are giving better and more expensive work for the same money; more time is spent in securing a good likeness; more proofs are submitted; in fact, more than double the time and labour is expended in your behalf. Such answers as these should be made by photographers in a manly, straightforward way. It is but the truth, and, if rightly explained, will be admitted by any intelligent person who wants a sitting. If any doubt arises, ask the first customers if they do not think very great improvements have been made in photographs. Invariably they will answer in the affirmative, thus admitting the pictures to be worth more. Seemingly, people have a mania for cheapness; some photographers, thinking it genuine, have catered to this feeling, and resorted to numerous devices, hoping to scoop in the public by clubs, or offers to give away a large picture if some one would come and buy a dozen small ones at one dollar or less per dozen. All this "clap-trap" style of doing business has failed in its object, and those who have entered into it are dissatisfied and convinced that it was a poor investment; at least this is true of those cases that have come under my observation. Many, if not all, of them would be very glad if they had retained their former prices; but how are they to get them back? The present dulness must sooner or later pass away, and then a better feeling will pervade all lines of trade, and those people that have abstained from sitting for pictures, even though the price has been so low, will come to the front, seek out a good artist, and be perfectly willing to pay a fair price. Unfortunately, one photographic fool makes many; advice to them is thrown away; they must suffer the consequences of their own folly. I only hope to call the attention of others to this fact, that, as no man can say to himself, he alone has advanced the art and science to its present perfection, what right has he to reduce the standard price? Morally he has none, because each and every one is indebted to the other. The individual knowledge possessed by any member of the profession has been derived from a common fund, to which all have contributed, thus creating a moral obligation, which should demand a united consideration. I consider it unprofessional for any photographer competent to do good work to injure the standard values by reducing the price; he should remember that there are others to whom he is indebted, and consider the question well before doing them so grave an injustice. These remarks seem pertinent to the welfare of our calling, for it is said that in union there is strength. If we only stand by each other, what necessity can there be for lowering our prices? The public is constantly demanding better pictures; we, by study and costly experiments, are striving to meet this demand; each improvement adds something to the cost of a picture, reducing the profit on our labour. These improvements are constantly being made, thus adding to the cost of photographs year by year. Does it not seem a suicidal policy to think of taking a backward movement regarding prices? Surely the inference drawn from the facts here presented is most positively opposed to any reduction. The peculiar character

* *Mosaics*, 1879.

of our calling, it being more strictly a profession than a business, is opposed to any tendency to cheapness, for if a man is selling the results of his talent, and holds them cheaply himself, who is to value them?

In concluding these hints, and leaving them to be digested by the craft, I would add, as a palatable dessert, that several who have cut under to such a degree are now anxious to sell their traps and hide themselves ostrich fashion.

POLICE PHOTOGRAPHY.

THE Paris Correspondent of the *Baltimore Sun* writes :

"Coming by the back of the Champ de Mars to-day, I was attracted by a group around a photographic policeman who was making rather an awkward effort to take a picture of an old house where an aged woman had suddenly died. I inquired into the subject. It appears that the poor old soul at eighty-seven years of age put out her lamp of life sooner than was expected by her neighbours. A young man had disappeared, and so had a few hundred francs. The police were put on the *qui vive*, and the first thing they did was to photograph the cold old corpse, and then the house. Now they are looking for the missing youth to take his picture. It is amusing to see the varied uses that photography performs among the Paris police. First of all they photograph themselves, from the highest to the lowest. Then they photograph some of their relations, and perhaps friends. They photograph all their first and second-class prisoners. In the exhibition their "rogues' gallery" is quite an array of celebrities, and would form a volume of sketches. Photography is applied in all cases of murder as to persons and places. Before the murdered body is moved, it and all the surroundings become carefully photographed. This is done by a special number of the police in uniform, whose entire work is devoted to the subject. Photographs of grand masters of the art of roguery and rascality are exchanged between the police chiefs of all nations. Thus to-day you can see some portraits of the wayward sons and daughters of Baltimore, Washington, Richmond, New Orleans, Charleston, &c., in "places of honour" on the line of the Paris police fine-art gallery. They are numbered, and this number is in an index, historical and descriptive book. The days of the dark-lantern with the police are changed into hours of the camera, but not camera *obscura*. I am told that the list of crimes detected through the agency of photography is an extremely long one. See to what detective purposes has the original idea of the long lost Daguerre come at last! Instances of forgery are numerous as being detected by photography. The Bank of France has a special photographic and scrutiny department for the detection of forged notes, bonds, &c. But its invisible portrait gallery for taking the likeness of a person without that person knowing it is unique and full of anecdotes. On one occasion a distinguished-looking person came to the bank desk and presented a little package of bonds of a certain English loan. The bank clerk did not readily relish the looks of the bonds, though those of the person were quite the thing. Stamping a little hand-bell—a signal for the photographer, who has his gallery in clear range of the applicant's desk, yet so constructed that it is not easily seen—the clerk engaged the stranger in conversation about the bonds, and in such a way that the photographer should have a good view of his face. This time a country school-master, as honest as the sun of day, thrust his face in by the desk, and he was photographed in company with one of the greatest forgers of France. The sensitiveness of photography is illustrated at this bank when ink marks invisible to the eye on the original document become quite plain on the photograph. You cannot alter, by writing, any paper, but photography will detect the "meddlesome pen" sooner or later. An erasure on the paper, if done ever so smoothly, is discovered by photography. The character and style of chirography is also

well tested by photography. Photograph some of the letters in a sentence, enlarge the photograph, and you have "a big guide" as to style easily followed and made a criterion. The post-office department here has its photographic director, and many a letter is opened, photographed, compared, and stored away for future evidence. Surrounded by such agencies, how well "honesty being the best policy" is proved to us! In the Exhibition you can see some instances of visitors there being unconsciously photographed. One old lady, however, discovered the police at their proceedings. Up she bounded, over went not only her chair, but the three near-by ones; down she dashed her umbrella, down she pulled her veil, and up she pulled her skirt over her head, and turned her back in a triumphant air up to the rash policeman. "What!" she exclaimed; "taking my portrait for a prison! O Jule, Jule, where art thou?" I am sorry to say her spouse Jule was in the arms of Morpheus, and cared not for photography. She went and demanded reparation, and was mollified by getting her photograph of her enraged self.

A PHOTOGRAPHIC ACTION.

ROSENBAUME v. AVERY—IMPORTANT DECISION.

THIS was an action brought in the Bloomsbury County Court on Friday last, before Mr. Judge Bacon, in which the plaintiff, an artist, sued the defendant, a photographer carrying on business at Ladbrooke Road, Notting Hill, to recover the sum of £50 for the loss of a testimonial sent to the defendant by a boy in the defendant's employ to copy and mount.

Mr. Atherly Jones, who appeared as counsel for the plaintiff, in opening his client's case, stated that he was an artist, and a well-known chess-player, and that in September of last year the boy in question called upon him for an account, and to whom he gave a cheque, and at the same time the testimonial, the subject of the present action, with instructions to inform the defendant that the plaintiff would call upon him and say fully what he required to be done.

The Plaintiff, being called, corroborated this statement, adding that he had made repeated applications for the roll, and, not being able to get it, had recourse to the present action to recover the estimated value of it.

This evidence was supplemented by that of William Freedan, who said he was a messenger in the defendant's service, although he had been subpoenaed by the plaintiff, and interviewed by the plaintiff and his solicitor, and had been to the defendant's house and given information since that, and had talked the matter over with the defendant. He said, he was instructed by the defendant on the day in question to collect account for him from the plaintiff, Mr. Lenthall, photographer, and others, and was allowed to bring goods home to the value of £1 or so.

The evidence of Herr Zerkert, the champion chess-player of the world, went to show that although the testimonial was of no intrinsic value, it was of inestimable value to the plaintiff, as it could not be replaced.

These being the leading facts of the plaintiff's case.

The Defendant said he never had seen the testimonial, which must have been lost by his boy, who had no authority to bring away from his customers goods of so great a value. He had, in consequence of receiving a threatening letter from the plaintiff, denied his liability, as he did not recognize the boy being his agent in the matter.

At this stage of the case the learned Judge came to the conclusion that in reality the boy was the agent of the defendant, but that the agency was a limited one, and the matter in dispute was merely one of amount; and recollecting that the boy was empowered to bring home goods to the amount of £1 or so, the justice of the case would be met by giving judgment in favour of the plaintiff for £1, although he could not dismiss the case without thinking that there had been some negligence in entrusting an article of such value to so young a boy.

A GOOD ADHESIVE MATERIAL.—Water, 1 ounce; methylated spirit, 2 ounces; dextrine, 2 tablespoonfuls. Mix the water and spirit; stir in the dextrine, making a smooth paste, and place the vessel you make it in in hot water till a clear brown solution results.—*Scientific American*.

EFFECT OF TOBACCO SMOKE ON SENSITIVE FILMS.

A CURIOUS circumstance, which is worthy of record and comment, recently occurred at a meeting of the Photographic Society of Berlin. Our esteemed correspondent, Professor Duby, read a paper, accompanied by specimens and experiments, on "Positives, their Different Methods of Preparation." He presented a number of beautiful examples. Finally, he undertook to show the practical working; but the paper, charged with bromide of silver, instead of yielding clear and beautiful prints as formerly, now gave only foggy, indistinct pictures, which at first could not be accounted for. Dr. Harnecker, however, suggested that the trouble was due to the tobacco smoke that during the lecture had filled the room. This conclusion was agreed to by all present, and the general opinion was that it would be quite impossible, under the circumstances, to obtain good prints.

Notwithstanding the general agreement of the meeting as to the baneful influence of the tobacco fumes, it must not, we think, be taken as a proved fact that the smoke of tobacco has this prejudicial influence on the prepared plate. Among professional photographers it is, we apprehend, scarcely likely to be tested, as smoking whilst operating would suggest a lazy mode of working scarcely conducive in any way to success. With amateurs it is different. An easy, leisurely mode of proceeding is indispensable to the enjoyment of a hobby; and the devotee of the Nicotian weed will proceed about many photographic operations with increased enjoyment when it is accompanied by a choice Partagas or a well-blackened pipe. That no harm need be feared is, we think, vouched by the experience of many very able amateur photographers. One of the first and best among these, Dr. Diamond, we have often seen with cigar in mouth whilst developing a plate, and we never saw or heard of any injury resulting. Amongst more modern amateurs there is none to excel R. Manners Gordon, the prince of neat manipulators as well as of artistic photographers. We have never seen him in his dark room without a cigar in his mouth, a circumstance which probably conduced to the deliberation of development to which he attributed a good deal of success. Many other cases might be cited; but these will serve, we think, to prove that whatever evils may be attributed to tobacco, injury to photographic plates is not one which can be legitimately alleged.

The circumstance of smoking being permitted during the progress of a photographic meeting will surprise English readers; but tobacco and beer are, we understand, not uncommon accompaniments in Fatherland to the discussion of scientific subjects. Whether this country would gain by following the example is doubtful, but it might be worth consideration.

PHOTO-CHROMO MINIATURES.

WE have very often brought under the attention of our readers methods of producing effective coloured pictures by colouring at the back of the print. A method of this kind has been recently introduced as a secret process, for details of which a fee has been charged. A similar method has been introduced by Messrs. Barnard and Son as "Chromo-Photography, invented by H. Krauss." Boxes of materials and colours for the operations are supplied by this firm, who give the following instructions. With skill and perseverance good results may be obtained by the use of ordinary materials; but for those wishful to obtain good results with little trouble, we may mention that boxes with every requisite may be obtained of this firm for a guinea. Here are the instructions:—

"Take an unmounted, rather strong print (photograph), and trim the same somewhat smaller than the convex glass to be used; wet it thoroughly in clean water, and then lay it, face up, on a sheet of glass or porcelain dish, blotting off the water; then spread over it with your finger some of the prepared paste, and apply the same also on the inside of the convex glass, which ought to be carefully cleaned; then pick up the picture, and lay it face down into the glass, and on the top of it a piece of smooth tough paper, and rub out all the paste and air-bubbles with the sharp edge of the squeegee, holding the glass in your left hand, so that you can see the picture, and the tool in your right hand, pressing the thumb against the edge of the glass, work from the centre, using but slight pressure, and frequently change the paper on the back, which serves to protect the print from getting scratched and torn. After the print is perfectly mounted, without showing either wrinkles or blisters, let it dry thoroughly, but spontaneously. Then grind the paper partly off on the back with fine sand-paper, and immerse it in a small tin pan containing the transparent medium, and melt the same on a lamp or stove; a good plan is to have the pan fitted into another pan, holding a hot water bath, which keeps the medium in a molten condition a long time, without heating too much, in which case it would affect the colour of the picture, turning it yellow. It will only take from twenty to thirty minutes to make the picture perfectly transparent; then take it out of the pan, and clean the glass side first (*the inside allow to cool off a little*), and with a coarse rag rub off all the surplus of the medium, laying the glass on a small cushion to avoid breaking. Now the picture is ready for painting. All white draperies—such as collars, laces, shirts, &c., also the corners of the eyes—are painted on the back of the photograph with permanent white; while painting, lay the picture on a sheet of white paper. Jewellery, lips, eyes, flowers, and small things of the kind, are also coloured on the picture itself, only care has to be taken to keep exactly the outlines. When this part is done, take a second convex glass, put it over the photograph on the back, and fasten the edges together with adhesive paper, holding the glasses together with spring clips; now mix the flesh colour, and on the back of the second glass paint over the face, also the hair to make it the tint and shade desired; the same is to be done with the drapery, dress, backgrounds, and all other parts of the picture; when part is painted, turn over, lay the picture on a white paper and judge the effect; any alteration can easily be executed by wiping the paint off with a rag. As a rule, mix all the colours on the second glass with white, to make them perfectly opaque, while in colouring the lips, hair, dress, &c., on the first glass, mix the colours with some of the oil, to keep them transparent; don't apply too much colour, and keep your brush almost dry. Special instructions for mixing colours for complexion, hair, &c., are found on each box of colours. Clean the brushes with turpentine, or soap and water. When the picture is painted, back with cardboard, and frame it.

"Sometimes the picture refuses to become quite clear and

transparent, showing some grey, opaque spots; these can easily be removed by scraping with the sharp edge of the squeegee while the whole is lying in the pan. These spots are caused by the paste which remained between paper and glass. Instead of the prepared paste, a good, well-boiled, stiff flour-paste can also be used with success. If the paste should dry too quick while mounting the picture, wet it again, and work it over once more with the squeegee, to remove all the paste.

"Photographs having light spots can easily be retouched with oil or water colour (india-ink mixed with a little carmine and blue); this work must be done on the back of the picture, after it is transparent. If you want to use mounted photographs, they must be taken off the mount; to do this perfectly, soak them in warm water about fifteen minutes, then lay them in a flat porcelain dish filled with water, and press them face down against the bottom of the dish with your left hand; with your right hand take hold of the cardboard, carefully peeling and rolling the same backward: never touch the picture itself. Photographs that are waxed on the surface must be washed thoroughly with benzine or ether, to dissolve the wax, before dismounting. If you do not succeed in anything during the work, read these instructions over again carefully, and you will be sure to find out the trouble."

SPECTRUM PHOTOGRAPHY.

Our readers will scarcely look to the columns of a daily newspaper for discussions on the technics of photography. We find, however, this in the *Times* of a few days ago:—

SIR,—In the article in the *Times* last week on recent developments of photography, it was stated that it has been found that by adding aniline colours to the sensitive film in spectrum photography the lines corresponding to the colours added were brought out in the negative. This was at first claimed by Vogel, but careful experiment proved that there was no such effect from the addition of any colouring matter. I had the pleasure of trying a series of experiments with Mr. Lockyer in his laboratory at South Kensington, strictly according to Vogel's directions, and they utterly failed. It was found that certain substances did, however, increase the sensibility of the salts of silver to lines not readily to be obtained without them; but this had no relation to their colour, as the most marked effect was shown with colourless alkaloids.

Professor Draper, of New York, showed, however, that the whole spectrum was photographable by employing an ingenious mechanical arrangement for shutting off the most powerful lines when they had done their work, and letting the light continue to act on the weaker. His father, Dr. Draper, had done the same thing at an earlier date on the Daguerreotype plate by availing himself of the well-known reversing action of light on iodide of silver.—Yours truly,
W. J. STILLMAN.

Florence, January 1st.

A subsequent issue of the same journal contains the following reply from Captain Abney:—

SIR,—I see in the *Times* of to-day that my friend Mr. Stillman throws a doubt on the action of dyes on a collodion film. I am quite at one with him regarding the theory that Vogel holds, but I am bound to say that in many instances the dye does give a power, to the film which it does not otherwise possess. The addition of a dye often produces a silver compound which is impressionable by any light which it may absorb; and there are dyes which in themselves bleach in light and become oxidized, as the fair sex know to their cost. The first class of dyes, when combined with silver, are amenable to ordinary development. The latter class, when oxidized, have the power of attracting freshly precipitated silver, and thus an image in silver is built up. If Mr. Stillman consults the various photographic periodicals of the last two or three years, he will find that I have described these actions of dyes at considerable length.

Professor Draper's method of photographing the "non-actinic" rays I have never been able to succeed with; but Dr. Draper's excellent plan I have frequently employed, and I have had the good fortune to explain its theory and to enlarge its applications.—Yours faithfully,
W. de W. ABNEY, Capt. R. E.

Kensington, January 7.

FRENCH CORRESPONDENCE.

NEW METHOD OF RETOUCHING NEGATIVES—RUSSIAN PYROXYLINE—ARTIFICIAL LIGHT IN PHOTOGRAPHY—RECENT PROGRESS IN SOLAR PHYSICS.

New Method of Retouching Negatives.—On Friday last, at the meeting of the *Societe Francaise de Photographie*, M. E. Lanry read a paper on a process for retouching negatives by quite a novel method. It depends essentially on the use of a new product—collodion stained red with orchanet. When the back of the plate is coated with this red collodion, the negative can be retouched to a considerable extent, and very artistic work can thus be produced. The back of the negative to be retouched is first coated with an albumen substratum composed as follows:—

The white of 3 eggs	90 c.c.
Water	75 "
Liquid ammonia	50 "

This must be well shaken, and the following mixture is then gradually added by small quantities at a time—

Sulphuric ether of 62° or 65°	...	100 c.c.
Alcohol of 36° or 40°	...	50 "

The white of the eggs must be beaten to a froth in the water, in order to separate the coaguline. The more ammonia that is used the larger is the proportion of ether and alcohol that can be added to the mixture without coagulating the albumen. All these substances—the ammonia, the alcohol, and the ether—are only used to make the albumen keep good for a long time, to facilitate its application to the glass, and to promote its desiccation. The ether and the alcohol should be added after the ammonia, and not until the latter is well incorporated with the albumen. The mixture is then allowed to stand, and when it is freshly prepared the ether will be seen to separate and to rise to the surface; under such circumstances it must be well shaken, that an intimate combination may again take place. But at the end of a fortnight from the first preparation the ether will no longer separate. Before employing the liquid it should be filtered through filtering paper, and it will then keep for an indefinite period of time without decomposing. For coating the back of the plate with the mixture, a soft brush may be used, or it may be flowed over the plate in the same way as collodion. When the negative has thus been coated, it must be placed in a vertical position on a draining rack to dry, and must be left there for from ten to twenty minutes. Over this substratum must then be flowed in the usual way the red collodion, the formula for which is given further on; but in doing so great care must be taken to prevent any of that substance from running over the edges and on to the face of the negative, for the latter would be stained by it. This collodion is prepared as follows:—

Ethereal tincture of orchanet (filtered)	...	100 c.c.
Alcoholic ditto ditto	...	50 "
Low temperature pyroxylin	...	1.5 gramme

The ethereal tincture of orchanet can be made by filling a wide-mouthed flask, well stoppered by a cork, with tolerably dry roots of orchanet and sulphuric ether of 62° or 65°. The roots are allowed to digest in the ether for a day or two, shaking them from time to time; the liquid is then left to stand for twelve hours, and is afterwards filtered through filtering-paper into a narrow-necked flask. By a similar method the alcoholic tincture of orchanet may be prepared, substituting only alcohol of 36° or 40° for the ether. This tinted collodion may be coloured more or less deeply by adding to it ordinary collodion. After the negative has been treated in this way, any part of it that may be wished can be reduced or decolourised by means of a brush of sable or badger hair, which is dipped in alcohol of 40°, and applied to the part

in question. In performing this operation, one must be guided pretty much by taste, and in this way weak negatives can be intensified, and vigorous ones reduced, as may be requisite. For portraits the method may be adopted in giving greater brilliancy to good negatives, in diminishing the effects of light on the figure, and in inserting details in white garments, or in the hair, &c. For landscape negatives it can be employed in bringing out more strongly the details of foliage, &c., in separating the different planes of perspective, and in lowering the very high lights. In those parts of the collodion that have been decolourized, a still greater effect may be produced by skilful scraping. To prevent the outlines of the decolourized portions from printing too hard, they can be lowered or softened by a brush moistened to the requisite extent in alcohol, and the outlines of the parts that have been scraped can also be softened by hatchings executed with the point. A large dry brush should always be kept at hand to sponge up the solvent as soon as it has produced the required effect. With a brush dipped in the alcoholic tincture of orchaet the film of red collodion may be made to take up a still greater amount of colour by spotting, which will have the effect of intensifying the corresponding portion of the negative. Lastly, by means of a soft brush, the film of red collodion, applied to the plate and worked upon as has been already described, can be again overlaid with a fresh film of the albumen solution, whose formula is above given; this acts as a sort of varnish, and gives the back of the negative a power of resisting the rubbing to which it is subjected by the thick glass plate of the printing-frame.

Russian Pyroxyline.—At the same meeting, several specimens of Russian pyroxyline, the introduction of which into this country is due to M. Warnerke, were exhibited to the Society.

Photographs by Artificial Light.—An English photographer, whose name escaped us, at the same meeting, called the attention of the members present to the *Lucograph*; it will not be necessary for me to describe this instrument, as it is already well-known to the readers of the PHOTOGRAPHIC NEWS. Speaking generally, however, I may say that in Paris, at all events, the minds of the best photographers are much occupied with the subject of artificial light for use not only in photographic printing, but also in the production of negatives. Numerous experiments with this object have been carried out in several of the laboratories, and more especially in that of Pierre Petit. Of course it will be of great advantage to those establishments where printing is extensively carried on to be able to prolong the day, and to utilize the evenings and nights that are so long at this season; but my own belief is that even on the shortest days, the portrait photographers enjoy quite sufficient solar light to satisfy the demands of their customers. Nevertheless, these experiments are highly interesting for our profession, and I propose to recur to them at greater length in a future letter.

Recent Progress in Solar Physics.—The Year-Book of the *Bureau des Longitudes* for 1879, which has just been published at the library of Gauthier-Villars, contains an article by M. Janssen on recent advances in solar physics. The illustrious director of the Observatory for Physical Astronomy established at Mendon, gives a prominent place in this article to the important part that photography plays at present in scientific researches, and he describes the numerous results obtained by its means. He has illustrated his remarks by adjoining to his article a double plate printed by the Woodbury process, representing two images of the same region of the sun's face, taken at an interval of fifty minutes. These two plates demonstrate in a remarkable way the rapid changes in the reticulations and granulations of the photosphere.

ERNEST LACAN.

ON THE ADDITION OF SODA OR OF YELLOW CHROMATE OF POTASH TO THE CHROMATE BATH IN THE CARBON PROCESS.

BY DR. J. M. EDER.*

THE addition of soda or of yellow potassium chromate to the chromate bath of carbon tissues has often been suggested of late. Opinions, however, differ on the subject: on the one hand it is asserted that certain advantages are gained by the addition: on the other, it is declared to be of no use.

Before coming to a conclusion on the point, it may be as well to have a clear idea of the action of the yellow potassium chromate.* As I have explained in my prize treatise "On the Re-action of the Chromates on Gelatine" (see PHOTOGRAPHIC NEWS, vol. xxii., 1878, p. 555), carbon tissue sensitised in a 3 per cent. solution of yellow potassium chromate is from twenty to fifty times less sensitive to light than when the bichromate is used. On the other hand, the chromated pigment paper is much more durable in the first case than in the second—it is much less liable to become spontaneously insoluble in the dark. This enhanced durability is the principal reason that many authorities give for recommending the addition of sodium carbonate to the chromate bath, in order to obtain successful results with the carbon process, more especially in summer.

The chief effect of such a restraining of the potassium bichromate is equivalent to a removal of some of the active part of it, for each molecule of neutralised bichromate has in a great degree lost its sensitiveness to light, and is therefore very slightly active during the process. Whether one-half of the bichromate is restrained with soda, or the solution is diluted to the extent of a half, the same result is obtained.

Restraining the chromate bath with ammonia has also the effect of rendering the sensitised carbon tissue more durable, without injuring its sensitiveness to light; the chromated gelatine is rendered much less effectively durable, and becomes more freely insoluble in the dark, than when soda has been used. In some cases the addition of soda or of yellow potassium chromate to the chromate bath is of positive advantage.

When the employment of a *strong* chromate bath seems advisable—that is, when *soft* copies are wanted, especially in printing from hard negatives in dull winter weather—then neither sodium carbonate nor yellow potassium chromate should be added, but only a few drops of ammonia, otherwise the chromate bath will become too weak, and will act like one that has been too highly diluted. But if it be necessary to work with a *weak* chromate bath—that is, if it be required to produce *harder* copies, particularly when printing from very soft and very thin negatives, in the hot and damp weather of summer—in that case, it is often of advantage to moderate the action of the potassium bichromate by adding soda or yellow chromate of potash. The same end can be attained by diluting the bath; but restraining with soda gives more delicate pictures and finer half-tones. It appears to answer the purpose better to have in the film, in addition to the very dilute and sensitive bichromate, a moderate quantity of the less sensitive monochromate, and thus to obtain a shallower impression than when the dilute bichromate alone is used. The addition of soda also prevents, up to a certain point, the formation of reticulations in the carbon prints.

In summer, and in hot close weather, when the sensitised paper is liable to spontaneous decomposition, and when more especially soft negatives have to be copied, I recommend the addition of soda to the chromate bath rather than diluting it. About so much dry (calcined) soda must be added as is equivalent to one-third or one-

* *Photographisches Archiv.*

* Or, to express it chemically, potassium monochromate; by mixing potassium bichromate with soda the homologous salt sodium monochromate is formed. Both salts have the same action.

half of the bichromate bath. When the bath is newly prepared, the following solution may be recommended:—

Potassium bichromate	...	4 to 5 parts
Calcined soda	...	1 to 1½ "

Dissolve in 100 to 120 parts of water. A mixture of about three parts red chromate of potash with one part of yellow produces the same effect.

In conclusion, I desire to draw the attention of my readers to Liebert's remarks on the same subject in his highly interesting work *La Photographie en Amerique* (3rd. edit., 1878). His directions are to immerse the carbon paper for from one to four minutes, according to the temperature, in a chromate bath of 2 per cent. in summer, and 3 per cent in winter,* to which—if it happens to be acid—1 or 2 drops of ammonia to every 100 c.c., or 1 or 2 c.c. of a concentrated solution of soda, must be added. As these additions lessen the sensitiveness of the chromated gelatine,† they must, if possible, not be resorted to in cold weather—that is to say, when the carbon paper is easily soluble, and especially when the negatives employed are weak. But when very intense negatives have to be printed from, the following bath is to be preferred:—

Potassium bichromate	...	2½ grammes
Mono-(yellow) chromate	...	2½ "
Water	...	75 c.c.
Alcohol at 36°	...	25 c.c.

The two latter ingredients must be mixed‡ before the salts are dissolved in them. Liebert previously crystallizes the salts from solutions in order to remove any traces of chromic acid and chrome-alum, but, according to my own experience, this trouble is quite unnecessary.

It will be seen that Liebert only has recourse to the yellow chromate in summer, though he uses more of that salt than corresponds to the addition of soda that I have given above.

We are also agreed on the durability of the carbon papers that are sensitized with this substance. But, on the other hand, I differ from Liebert as to the condition of the negative. I recommend a bath containing potassium monochromate, or soda, for thin and weak negatives, while Liebert advocates it for intense negatives. My own views I still hold to be correct, but should like to ascertain the opinions of other photographers on this point.

Correspondence.

SUBSTRATA FOR DRY PLATES.

DEAR SIR,—In finally arranging THE PHOTOGRAPHIC NEWS for the past year, prior to sending them to the binder, I quite accidentally alighted on page 273, and read a very interesting article on a "New Substratum" contributed by Mr. Henry Cooper; by some unfortunate and unaccountable reason I missed the article when it appeared, or I should have written thee what I now write.

In 1873-4, prior to the "Transit of Venus," and the selection of a dry plate or emulsion process that could be relied on for that work, I had, in conjunction with others, to devote much time and attention in endeavouring to obtain a thoroughly faultless and reliable substratum. Experiments were carried out with various substances, such as india-rubber dissolved in pure chloroform; dried albumens and gelatines of several strengths, in various menstrua; whilst gelatine and albumen were separately

treated with nitric acid, tannin, and chrome-alum, for the formation of an insoluble substance. The latter, when added to the gelatine and albumen, was discarded, owing to the colour it imparted to them, being sometimes of a pure tint, and was thought at the time would be detrimental to the transparent parts of an otherwise good negative. After various trials with the numerous experimental substrata, it was finally decided to use the formula published at the time, viz.:—

Albumen...	...	10 grains
Distilled water	...	10 ounces
Liquor ammonia fortis...	...	1 drop

Applied with the valuable brush introduced for that purpose by Mr. Valentine Blanchard. It will thus be seen that chrome-alum added to gelatine was used as a substitute prior to the date recorded by Mr. Henry Cooper in the article referred to.

It is reluctantly I bring this forward; but I do so in the most friendly manner, not with the object of detracting one jot of credit so justly due to Mr. Henry Cooper, who publishes without reserve his highly interesting researches and instructive results, as he has done in the present case, having published fully a substratum for practical use; still, I think it is only right to show that the same experiments have at a previous period had a fair trial in totally different hands, emanating from another independent source—in fact, to different persons marching over the same ground, at different periods, though with variable results.—Yours truly,

WM. B. DOYLE,

Quarter-Master Sergt. Instructor.

Photo. School, S.M.E., Chatham.

PHOTOGRAPHY BY MEANS OF OXALATE OF IRON.

SIR,—It is against my wishes to prolong a controversy with an anonymous writer, but I cannot refrain from pointing out how weak is the case of "Historicus."

In my last letter I gave the reasons for my holding the opinion that Dr. Draper used the ferric oxalate photometer, and that he also produced, if not the first photograph, at all events, one long prior to Dr. Phipson. I still hold the same opinion, for I certainly shall not doubt Dr. Draper's word, although I do not refer to the original memoir. *Assuming, however, that Dr. Draper has made a statement which is not true*, there still remains Hunt's statement regarding his own production of pictures with ferric oxalate to be disposed of by "Historicus," before the claim on behalf of Dr. Phipson can be admitted. I have already given the date of the publication of Hunt's work (viz., 1854), so that a photograph by the aid of ferric oxalate must have been taken some six years before Dr. Phipson began his experiments. I may remark that the fact of my not having the latter gentleman's papers by me cannot affect the question of priority, and I fail to see that it can detract from the credibility of the statements I made and still adhere to.—Yours faithfully,

W. DE W. ABNEY.

SIR,—Your correspondent "Historicus" appears somewhat too positive in his assertion that the first picture in oxalate of iron was produced by Dr. Phipson in 1860. It is at least certain that the capabilities of this salt were known and published prior to 1860. I have before me "A Manual of Photography," by Robert Hunt, third edition, 1853. Chap. IX. of this work is "General Summary of the History of Photography," and states: "It is thought that it may prove of some interest to append the following table, compiled with much care for the British Association, by the author, and printed by that body in their reports for 1850, and to which now numerous additions are made. It is believed that the dates of discovery are accurately given, the date of publication being, of course, in all cases taken where there was the slightest doubt." Then follows list of the metals, with their salts, &c. I give the one headed "iron."

* Quite contrary, therefore, to the rule which prevails among ourselves: "Strong baths in summer, weak ones in winter."

† My own experience showed that this statement is true for soda only, but not for ammonia.

‡ In my own formula, alcohol can also be added, and, indeed, I recommend the use of it.

Iron, protosulphate of	Hunt ...	1844
„ persulphate... ..	} Herschel .	1840
„ ammonia-citrate		
„ tartrate of		
Attention was first called to the very peculiar changes produced in the iron salts in general by	Herschel .	1845
Iron, cyanic compounds of	Scheele ...	1786
„ (prussian blue)	Desmottiers.	1801
„ ferrocyanates of	Fischer ...	1795
„ iodide of	} Hunt ...	1844
„ oxalate of		
„ chromate of		
Several of the above combined with mercury	Herschel...	1843

It appears certain from this list that the photographic properties of the oxalate of iron was published prior to Dr. Phipson's experiment, and cannot, therefore, be claimed for him as *original discoverer of its properties*.*

I may also call attention to the fact that Herschel mentions the peculiar properties of oxalic acid, in its power of precipitating gold, in his description of the process he invented by means of the ammonio-citrate of iron, and which he named the "chrysotype" process. He does not appear to have used the iron salt in combination, but the description might suggest a process similar to the one just invented by Mr. Willis.—Yours, &c., B. L.

CADETT'S SHUTTER.

DEAR SIR,—In reference to the letter of Mr. Vincent Hatch, permit me to suggest another method of supporting the velvet disk while focussing, when using the shutter inside the camera. I think that the following idea will be found an improvement on those of Mr. W. Barry and Mr. Vincent Hatch.

Place an ordinary stiff spring pinch-cock (such as is used in chemical laboratories) on the rubber tubing over the mouth-piece of the pear; when it is desired to keep the disk supported, squeeze the pear with one hand, and with the other slip the pinch-cock on to the rubber tubing just beyond the mouth-piece of the pear; the pear may now be let go, and the disk will remain supported, as the air cannot return.

The suggestion of Mr. V. Hatch with regard to reversing the angles of the pins supporting the disk is obviously good, for the reason he mentions; but I found out long ago that it could only be applied to very few of the cameras in general use, on account of the space occupied. I would suggest, therefore, that the camera be wiped out, before using, with a damp sponge, this would no doubt fix the dust.

To those who use the shutter outside, I would suggest that while the pear is being squeezed, the tubing be bent double, and held lightly between the thumb and first finger of the other hand; the disk can then be supported during exposure without holding the pear and cramping the hand. I mention this merely on account of the long exposures at this time of the year—the pear being made thick, so as to give a quick return in the case of children moving suddenly when being taken in a strong light.

Permit me to thank Mr. Barry and Mr. Vincent Hatch for the kind interest they have taken in my little shutter.—I am, dear sir, your obedient servant, JAMES CADETT.

MR. COOPER'S EMULSION.

DEAR SIR,—All photographers interested in dry plate photography will readily acknowledge and appreciate the obligations which Mr. Cooper has conferred upon them

* Our correspondent, in his interesting letter, overlooks the purport of the present discussion, which relates to the first production of pictures by oxalate of iron, not to the first knowledge of or suggestion of the photogenic properties of this salt. The photogenic properties of chloride of silver were known many years before they were utilized and a picture-producing process formulated. "He only discovers who proves," is a dictum of the highest importance. Suggestion is easy; but practical results, not merely tentative efforts, are of real value.—Ed.

by the publication of his Emulsion Process. There are one or two questions, however, that occur to me, and I have no doubt to many others, that Mr. Cooper would greatly add to our obligations by answering at his convenience.

1st. With regard to exposure. Of course it would be impossible to give any definite time, but some data might be given to go upon. On a fine day in May, for instance, to take a fine landscape with a No. 6 Portable Symmetrical lens with middle size stop, what time would be about right?

2nd. How or where does he obtain his syrupy lactate of ammonia? I cannot obtain it anywhere. To make it, would it be sufficient to allow the ammonia to act upon the sugar of milk, or is it got by a more elaborate means?

Next as to the emulsion. Seeing that the plates are washed and preserved in the ordinary way, would it not be as well to use the emulsion when ripe instead of washing and drying it; or is there any specific reason for the washing?

If Mr. Cooper will kindly trouble himself to answer the above questions, he will increase the debt we owe him, and especially your obedient SERVANT.

THE LUXOGRAPH TESTIMONIAL.

SIR,—From the remarks of Mr. Faulkner, he thinks I committed a breach of social etiquette by publishing his name without his sanction. So it would have been, had the demonstration been a private one, but it happens that it was quite public in every sense; hence I was justified in mentioning the names and quoting the opinions of those who were present, opinions that were corroborated by Mr. Gregson's manly and business-like letter.

I dismiss with a smile Mr. Faulkner's opinion of myself, which must have undergone a thorough revolution since he once did me the honour of telling me that he entertained the highest opinion of my commercial abilities, and made certain overtures to me respecting a business connection, out of which he proposed to take in my son as a partner, and found the firm of Lombardi and Faulkner for a consideration of £1,000.

In self-justification for having, if but for a moment, listened to such a proposal, I hasten to say that this was anterior to the famous background epoch, when a well-known gentleman dispensed a piece of chalk and a shoe brush to credulous photographers for the small sum of two guineas. I was one of the happy recipients of Fortune's favours, and I still scrupulously preserve the relics of what was to mark the new era of background art, but which ultimately proved to us to be a disastrous failure.

If Mr. F. endeavours to show that he suffered any loss by this only transaction I ever had with him, his remarks will not commend themselves to the reasonable appreciation of your numerous and intelligent readers. But if Mr. F. has not succeeded in persuading the discriminating readers of your important NEWS to believe what he conscientiously does not believe himself, he certainly hit the nail on the head by the information he gives them in his last paragraph—he actually found the philosopher's stone, and the way to subjugate the whole of Afghanistan without a single shot: he has discovered that the Luxograph offices are at 13 and 14, Pall Mall East, as if he thought that by advertising this fact in both NEWS and Journal, one would wish it to be kept as a secret.

The fact is, that Mr. Faulkner's repeated, unmistakable, enthusiastic, and eulogistic remarks of the famous evening of the Luxograph demonstration actually induced me to take the matter into serious consideration.

I owe my success in life to a determination I adopted from boyhood, of seeking the company of my superiors and following their advice. Fortune brought me into con-

tact with Mr. Faulkner, whom I always looked upon as a star of our profession. I heard his highly favourable remarks, and feeling that the commercial development of the Luxograph would prove a boon to my establishments, a great convenience to our customers, and an extra source of revenue to my exchequer, I secured three instruments at once.

I must therefore beg you, sir, to convey to Mr. Faulkner my grateful acknowledgment of his good advice, inasmuch as the Luxograph proved itself to be a very great success in every way.—I remain, sir, yours truly,
 LOMBARDI.
Pall Mall East, January 7th.

SIR,—As my name has more than once been mentioned in this affair, I beg to write a few lines. I was present at the demonstration of the Luxograph Light with Mr. Faulkner. The apparatus was in the crudest possible state, and many apologies were made and descriptions given by Messrs. Alder and Clarke as to what the future apparatus was to be. I heard Mr. Faulkner refuse to give a testimonial or order an apparatus until the improvements were made. A few days afterwards Mr. Faulkner thought he would fit up an apparatus with several alterations and additions, and he asked me to call on Messrs. Alder and Clarke to explain his intentions, and he asked to be supplied with a reflector and lamp; nothing else was required, no stand, or screen to soften the light, or chimney, or any fittings whatever. I think Mr. Faulkner's offer of £15 15s. most liberal.—Yours faithfully,
 DOWNE ROSS.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held at the Memorial Hall, Albert Square, on the evening of January 9th, Mr. CHARLES ADIN, President, in the chair.

The minutes of the previous meeting were read and passed, and Mr. Fred McClaren duly elected a member of the Society.

Mr. J. POLLIT, in reply to Mr. Brothers, said he had taken a negative of the interior of a large commercial establishment in town by the aid of the electric light; the negative was a good size. He used the wet process, and with a rapid rectilinear lens, with a three-quarter inch stop, and gave one hour exposure; and, although there were some rather deep shadows in the picture, they were not very objectionable, and owing to the very confined position in which he had to work, and the short time at his disposal, he was unable to arrange reflectors, &c. He was sorry he had not had the opportunity to make a print for the benefit of the members, but at the next meeting he would, he hoped, be able to show one. A long discussion followed upon the merits of the different electric lamps, regulators, and other apparatus.

Mr. J. C. SEWELL, who has of late devoted much time and attention to the subject of electric lighting, explained that he had seen a large workshop lighted by one regulator. The method employed was to put the regulator (or lamp) in a thing like a bucket suspended from and near to the ceiling. The whole of the illumination was therefore reflected from the ceiling in every part of the workshop, the light was excellent, and without objectionable cast shadows.

Mr. JAMES YOUNG then exhibited a transparency which he had printed by the light of the moon in sixty seconds on the previous evening. The plate was prepared with gelatine emulsion, and exposed in contact with a negative in the ordinary way.

Mr. ALFRED BROTHERS, F.R.A.S., thought this was a matter which should not be too hurriedly passed over. It was the first picture of the kind he had seen, and he was inclined to think that Mr. James Young would be able to produce a negative by the camera some fine night.

Mr. YOUNG said he thought so too, and promised to make a trial in that direction the earliest opportunity. He also introduced a very neat levelling stand, which he had constructed for use with gelatine or other plates.

Mr. J. W. LEIGH exhibited a collection of exchange prints from the prize negatives of the Amateur Photographic Society (London); they were all from wet plate negatives.

Mr. KNOTT said, with regard to the breaking of the glasses at each end of the flame chamber of the sciopticon, some people were more unfortunate than others, and he had been one of the unfortunate ones. He had, therefore, cut a slit at the top of the front portion of the body of the lantern, through which could be introduced the front glass, without removing the condensers. He found that by binding the edges of the glass with paper, if the glass did happen to break, it was kept in position, and he exhibited a glass of double length (or in duplex form), so that should one side break it could be easily reversed. Mr. Sewell, Mr. Coote, and several other gentlemen expressed surprise to hear of the front glass breaking, as it was most unusual.

THE SECRETARY read a note from Mr. Cussons, which was accompanied by a package of pocket almanacs kindly sent for distribution amongst the members, and a vote of thanks was passed to Mr. Cussons for his kindness.

Mr. J. W. LEIGH asked for a good rule or test for the comparative sensitiveness of dry plates, to which he received several replies.

THE PRESIDENT now introduced the subject of the annual extra meeting, and, after a conference with the Treasurer on the subject of finances, it was proposed, and unanimously carried, to have a knife and fork tea, at the next meeting of this Society, and that each member attending that meeting, whether to tea or not, pay two shillings and sixpence. It was decided to have a lantern exhibition.

Mr. AMBLER promised to read a paper, "Reminiscences of Photographic Experiences in Germany," and all members were earnestly requested to contribute as much photographic matter as possible.

THE SECRETARY said that, as usual, with lantern exhibitions of this Society, there would be a trial of members' slides on the evening before the meeting, and, to save disappointment, he begged to remind all present of the rule that no member's lantern slides could be shown unless received at the Memorial Hall on or before Wednesday, February 12th.

A vote of thanks was passed to the President and those gentlemen who had contributed to an interesting evening, and the members dispersed.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE third ordinary meeting of the present session was held in 5, St. Andrew Square, on Wednesday, 8th instant, Mr. LESSELS, the President, in the chair.

The minutes of the last ordinary meeting, of a council meeting, and a sub-committee meeting, having been read and approved, the following gentlemen were unanimously elected ordinary members of the Society: Mr. Malcolm Dunn, Mr. J. T. Johnstone, and Mr. Neill.

Mr. ROBERT MURRAY, C.E., then read a humorous paper, entitled "The Whisky-and-Water Process, a Northern Development of Mr. James Mudd's Gin-and-Water Process," in which the author satirized some of the shams connected with the process-monger and the pseudo-discoveries of would-be inventors. The paper was interspersed with anecdotes and local allusions, and was the source of much amusement to the members present.

Copies of "The Photographer's Pocket Almanac and Reminder" for 1879, sent by Messrs. Cussons and Co., of Southport, were distributed.

Talk in the Studio.

STREET PORTRAITS BY THE ELECTRIC LIGHT.—We are favoured by Mr. A. J. Jarman, of Ramsgate, with a couple of groups taken by the light of an electric street light, Westgate-on-Sea. As Mr. Jarman remarks, these are interesting as being the first out-of-doors night photographs—at least, as far as portraits is concerned—which have been attempted. The portraits are of course but dimly illuminated, but there are some curious points to be noted. The electric light itself, shown on one picture, is dark from the reverse action of light, the halo around being brighter than the light itself. The opal globe is seen as a dark globe with a white edging, and a vertical line in the globe produced by the fittings, dark as seen by the eye, is a white line down the dark globe.

"YOU DIRTY BOY."—Photography has made many persons familiar, who did not visit the Paris Exhibition, with a clever plastic genre study entitled "You Dirty Boy!" in which a dirty

little urchin is being roughly lathered and scrubbed, whilst his nurse objurgates him as a "dirty boy." We have received from Messrs. Thorpe and Watson a photographic burlesque of the same subject in which Lord Beaconsfield is administering the rough cleansing to the dirty boy Gladstone. It is clever, amusing, and not ill-natured.

OWNERSHIP OF SPECIMENS.—Mr. Richard Gay, representing the Staffordshire Permanent Portrait Company, Broad Street, Hanley, made an application to the Bench under the following circumstances:—Mr. Gay stated that he had discovered a process of transferring photographs on china, which he described as being more complete than any other process hitherto discovered. Some time ago he laid his discovery before Messrs. Powell and Bishop, manufacturers, and asked a certain sum and two free licences for the use of it. Terms were not accepted, but several pieces of china were lent him by the firm on which to transfer specimens for future consideration, it being a distinct understanding that if terms were not ultimately agreed upon the china on which the specimens were transferred should be broken. On the articles, however, being returned, the parties could not come to terms, but, instead of breaking the articles, Mr. Bishop said they were his property, and he should keep them.—Mr. Gay asked the Bench whether he could take action to enforce the destruction of the articles, as their existence in the possession of Messrs. Powell and Bishop might seriously interfere with any right of patent he might claim.—The Bench said that proceedings could not be taken in a Criminal Court, but damages might, perhaps, be claimed in a County Court.—Mr. Greenwood advised Mr. Gay to consult a legal gentleman, as the matter was not within the jurisdiction of a Police Court.—*Staffordshire Daily Sentinel*.

ARRANGEMENT OF PHOTOGRAPHS.—"Crowquill," writing in the *Queen*, says:—"A novel and very ornamental way of utilising photographs is to get a large sheet of cardboard, and cut it out into a large shape, either oval, round, or fancy; bind it with dark red or blue ribbon velvet, about two inches wide, and arrange the photographs all over, either in circles or some sort of regular pattern, first cutting them out in neat rounds or ovals. It is not necessary to float them off their cards, but only to peel the backs off. Use strong gum. When the whole is finished, tack two pieces of the velvet to the back, to hang the card to the wall, tying the ends into a good-sized bow where the nail is. I think many persons would be very pleased with these wall ornaments. They can be made as large or as small as desired. They are very easy to make. If they are required more ornamental, add a gold paper background, or paint a little round the photos. Screens for standing on a table are very pretty covered with photographs, and fans made of cardboard can be made without much trouble, and covered with them. I have seen cardboard cut into the form of fans, with a large coloured bow at the handle, covered with cartes, put up on each side of a looking-glass, and also used as hand fire-screens. Also I once saw the panels of a small boudoir ornamented with cartes, which really looked very well, and was most interesting to look at."

PLASTER OF PARIS.—Plaster of Paris may be made to set very quick by mixing it in warm water to which a little sulphate of potash has been added. Plaster of Paris casts, soaked in melted paraffine, may be readily cut or turned in a lathe. They may be rendered very hard and tough by soaking them in warm glue size until thoroughly saturated, and allowing them to dry. Plaster of Paris mixed with equal parts of powdered pumicestone makes a fine mould for casting fusible metals; the same mixture is useful for encasing articles to be soldered or brazed. Casts of plaster of Paris may be made to imitate fine bronzes by giving them two or three coats of shellac varnish, and when dry applying a coat of mastic varnish, and dusting on fine bronze powder when the mastic varnish becomes sticky. Rat-holes may be effectually stopped with broken glass and plaster of Paris. The best method of mixing plaster of Paris is to sprinkle it into the water, using rather more water than is required for the batter; when the plaster settles, pour off the surplus water, and stir carefully. Air-bubbles are avoided in this way.—*Scientific American*.

To Correspondents.

W. S. B.—We have not seen any comparative trial made of the two washing machines, and we are not, therefore, in a position to give any opinion as to which is best. We have the same facilities as our correspondent at p. 333333: the 333 furnished by reading.

WAXY.—We are puzzled as to the nature of your trouble. You complain that your paper negatives are too transparent after waxing. But what is the disadvantage of transparency in a negative? Do you mean that they lose printing vigour and contrast? If this be so, the fault is due not to the waxing, but to the original from which the paper negative is printed. If you find, however, that there is sufficient vigour before waxing, you need not fear to use it without waxing. There are various things may be used instead of wax, but they would all possess similar characteristics. Paraffine may be used, or castor oil, or, in fact, almost any similar body.

G. S. B.—At the time to which you refer, Mr. A. Brothers was a portraitist in St. Ann's Square, and is still. Mr. J. Mull was a portraitist in the same Square, and is, we believe, still. Mr. John Eastham was a portraitist at that time in St. Ann's Square, if our memory serve us right; but is now in Devonshire Street, Higher Broughton, Manchester. There were other portraitists, we think, in St. Ann's Square at that time; but we cannot recall their names.

W. H. M (Croydon).—The defect in your prints is imperfect fixation; and looking at the circumstances, we have not much hesitation in pointing to the cause: it is simply due to the exceedingly cold weather. We have often pointed out the fact that on a sudden fall in the temperature the ordinary hypo bath performed its office imperfectly. In such cold weather the solution should be warmed to a temperature of at least 50°, or from that to 60°. The same cause, inducing severe bronchitis, delayed the Editor's answer to your question.

H. H. SUNDERLAND.—A "formula" for enamelling is of no service without instructions, and these would occupy more space than we can devote to the subject in "Answers to Correspondents." You will find instructions in almost all our YEAR-BOOKS for some years past. In that for 1878 you will find instructions on p. 128.

NEGATIVE.—Almost every retoucher has his own especial method of preparing the surface of the negative so as to secure a tooth. Many, when they have the negative varnished with a hard spirit varnish, rub with a little powdered resin on the end of the middle finger until they have slightly dulled or roughed the surface of the varnish, which then presents a good tooth to the pencil. Some use a little turpentine in manner similar, instead of powdered resin. The majority, we believe, prefer a matt varnish. Such varnishes are various. The following is said to be good:—1 ounce alcohol, 4 ounces benzole, and 8 ounces ether, with about one-third of an ounce of gum mastic dissolved therein. This should be applied cold. And we should prefer the negative to have received a coating of very dilute gum water or gelatine, to avoid risk of injuring the collodion film.

B. R. S.—The primary cause of the grey tone and feeble character of the prints is the weakness of the negatives. With a feeble negative you cannot print sufficiently deep to get rich black tones; and in the attempt to secure such tones, you only secure flat prints, which are grey instead of black.

ARCHITECT.—The method of M. Pellet, by which direct prints in blue lines may be produced from a drawing, was described several times in our last volume. It is briefly as follows:—The sensitizing solution is composed of—

Oxalic acid...	5 parts
Perochloride of iron	10 "
Water	100 "

This solution can be modified according to the sensibility required. The oxalic acid can be replaced by any of the other vegetable acids. If the paper has not been sufficiently sized, gelatine, gum, isinglass, or dextrine can be added to thicken the solution. When dry, the paper preserves its sensibility very well, which sensibility is very great. In order to reproduce a map, a sheet of sensitized paper is placed under the map, and if in summer and in the sun, fifteen to thirty seconds is sufficient to decompose all the parts not protected by the black lines. By the action of the light the salt of iron is reduced into protoxide. This salt is not acted upon, as the former, by a solution of yellow prussiate of potash, therefore those parts protected by the black lines turn blue. After exposure, the paper is plunged into a bath of prussiate (15 to 18 per cent.), and immediately the design appears in blue. The paper is then rinsed in cold water, and plunged into a bath of chlorhydric acid (8 per cent.), in order to dissolve out what may remain of the protoxide, and to whiten the paper; the proof is then washed, and left to dry.

HOLLOWAY.—The most frequent cause of oyster shell markings is in the collodion, not in the nitrate bath, although certain conditions of bath will conduce to the result. But the most common cause is the use of a collodion giving a horny repellent film. Increased age in the collodion will cure this, as will the addition of a portion of a ripener and more powdery collodion. Sometimes the addition of a drop or two of distilled water to an ounce of collodion will effect a cure. 2. No; we prefer iodide of potassium. 3. As a rule it is only necessary to add a few drops of a plain solution of chloride of gold. At intervals it is desirable to add fresh solution made as the original bath was. An old bath generally tones slower and better than one newly mixed.

ROGER LAURENT.—Many thanks; and in our next.

The Photographic News, January 24, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PYROXYLINE AND ITS KEEPING QUALITIES—MANCHESTER IN THE CAMERA—PHOTOGRAPHIC ILLUSTRATIONS IN OUR BOOKS.

Pyroxyline, and its Keeping Qualities.—The discussion at the last meeting of the Photographic Society of Great Britain, touching the best means to preserve pyroxyline, will be read with interest by all those who are in the habit of preparing their own gun-cotton or their own collodion. Pyroxyline is very apt to emit acid fumes when kept in a dry state, and the giving off of these fumes, it must be remembered, is a sign of incipient decomposition. The employment of an alkali may be of use to begin with, to prevent the decomposition from being set up; but when once the material has begun to decompose, all the care in the world will not cause the gun-cotton to return to its original condition. A fuming pyroxyline, if you cannot employ it at once, is little use to keep. Moreover, it is a dangerous substance, and one that is well outside the photographer's laboratory. Our advice is to employ your pyroxyline always as soon as you can, and to keep in water any quantity you may have in stock. When military gun-cotton was first introduced into this country from Austria, an alkaline carbonate, in small quantities, was sprinkled over it, and the Austrians themselves took the precaution to dip the stems into a silicate, so that they might be covered with a coating of soluble glass. But none of these measures proved so effectual as the keeping of the samples in water or in a damp condition. There is, moreover, the great advantage that damp gun-cotton is inexplosive—nay, actually noninflammable—under ordinary circumstances. A fire in a house which contains wet gun-cotton would be a source of no danger at all so far as the pyroxyline was concerned, for this would simply smoulder, or burn by degrees as it got dry; but pyroxyline in its ordinary state would be exceedingly dangerous under such circumstances. In regard to military gun-cotton, which is very like photographer's cotton, this is found to keep its properties for years in a damp state, the generation of red fumes being almost unknown. The cakes or slabs of gun-cotton pulp—for it is in this form that the military authorities keep their pyroxyline—are stored in the magazines for years without any particular care, the only precaution taken being to examine the material periodically to ascertain if it is impregnated with a sufficiency of water. The gun-cotton sometimes becomes mildewed, and shows other exterior signs of long-keeping; but these have no material effect upon its properties as an explosive agent. The mildew is simply wiped off, and the wet slabs allowed to remain as they are. Of course, military gun-cotton is not absolutely the same as the photographer's gun-cotton. While the latter is wholly soluble in an ether and alcohol mixture—or, at any rate, should be so—the military substance is only soluble to the extent of ten, or at the most fifteen, per cent. Indeed, one of the methods for testing military gun-cotton is to wash it with ether and alcohol, and if it sustains a loss greater than the above, it is rejected. At the same time, it will hardly do, perhaps, to argue that what holds good with military pyroxyline may be taken for granted in the case of the soluble material. There is little doubt, we fear, that the photographer's pyroxyline is rather more unstable than the other. The difference in composition lies in the quantity of nitrogen that the two materials contain. Military gun-cotton is termed by chemists tri-nitro-cellulose, because it contains three atoms of nitrogen, whereas the photographer's cotton, which has but two, is called bi-nitro-cellulose. The latter would seem hardly so perfect a substance as the tri-nitro-cellulose, as far, at any rate,

as keeping qualities go, for certainly the issue of red fumes is more rife among samples of soluble than insoluble cotton. As we have said, however, we advise photographers to dissolve their pyroxyline as soon as possible, and keep it in the form of collodion rather than as pyroxyline; but if the material is to be stored, let them keep it impregnated with water, which has the effect not only of rendering the substance innocuous, but also of preserving it from decomposition. Warm weather acting upon dry pyroxyline in stoppered bottles is very liable to set up decomposition.

Manchester in the Camera.—A new book, which the *Athenæum* says is to be paid for by subscription, is shortly to appear, entitled "Manchester as It Is." The chief feature of the work will be a series of forty photographs representing the city at the present day, the pictures in question being printed in permanent pigments from negatives by Mr. Alfred Brothers. The photographs represent the salient points of Manchester, its public buildings, and prominent thoroughfares, and will consequently be a true and valuable reflex of the city at the present day. It is a pity, as we have several times pointed out in these columns, that the representation of our cities, and of London especially, by means of the camera, is not more frequently undertaken. There is, we are glad to see, an association formed for securing photographic views of "Old London," and many of the relics that are disappearing from our midst have been secured, so that a truly historical record of them may be preserved; but Manchester seems to be the first to consider a series of such photographs worthy of publication in a collected form. In London we might bring out two such works, "Old London," and "New London," the one to contain views of such buildings as remain to us from the last century and previously, and the other to represent what might be termed Modern London. In the first would be included views from some of the old houses still to be found in Holborn and Wych Street, pictures of the water-side taverns that still exist in Wapping, and of the inns and courtyards in the Borough, that remain to us as a remnant of the old coaching days, together with such of the public buildings and city squares which still retain their antiquated character. To illustrate modern London would not be so difficult, and a selection of photographs showing our new public buildings, broad streets, and open squares should find plenty of purchasers, if the work were well and tastefully got up. In the case of the Manchester book, we hear only two hundred and fifty copies are to be printed, so that others but subscribers will find it hard to get copies.

Photographic Illustrations in our Books.—Messrs. Sampson Low and Marston, who have identified themselves with the publication of books illustrated by photography, are issuing a volume by Mr. F. G. Heath, entitled, "The Fern World," with which the camera has had much to do. Mr. Heath's name is so well known in connection with ferns and their culture, that little need be said of the letterpress of the volume, and he has been wise enough, in order to secure pictures of fern gardens in nature, to employ the camera to transcribe them to his book. In some cases the photographs have been employed for drawing from on wood; in others, the reader has the camera picture itself before him. The fern studies chosen are exceedingly beautiful, and add a great charm to Mr. Heath's delightful book. Of Mr. Thomson's book on Cyprus, which Messrs. Sampson Low are also to publish, we have heard nothing lately; many of the photographs our readers may doubtless have already seen, for they were exhibited for some time at the Pall Mall Exhibition in November, and they certainly convey the best idea that has yet been given to stay-at-homes of the newly-acquired province. But Mr. Thomson and his publishers must make haste with their book, or the public will have lost much of their interest in Cyprus and Cypriotes.

ON THE FADING OF THE UNDEVELOPED PHOTOGRAPHIC IMAGE AND ON SOLUBLE BROMIDE IN EMULSIONS.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.*

I must apologise to the members of the Society for reading before them what may appear a rather theoretical paper, but I venture to submit that it is only by looking at every side of a question that we can arrive at the great desideratum—truth. I will bring forward to-night some thoughts regarding the shortcoming of emulsions in one respect, and suggest what is its cause. Perhaps I shall be rather discursive, but at all events I shall avoid giving “an interesting paper,” to do which, according to a certain distinguished Professor, I should have to commence with the Deluge, give a passing glimpse at the undulatory theory of light, whilst the peroration should contain allusions to the microphone.

In collodion processes we are far too apt to forget the vehicle with which we are dealing, viz., collodion itself. We are all, as a rule, particularly careful about the purity of our silver compounds, but are very apt to neglect the body in which they lie, unless it be to pay attention to the physical nature of the film itself. Regarding the chemical aspect of the film, beyond the silver salt which it contains, no sort of heed is paid, and in such an omission I think I can show that we run a serious chance of introducing one source of fading of the photographic image. It is not many years since that I had to order in a large stock of chemicals for Government, to fit up our photographic wagon, which is intended for field service. On the principle that the Controller of Stores at the Arsenal at Woolwich must have a sealed pattern of everything which he may have to issue (a most excellent plan in most cases, but hardly necessary in this), this supply of chemicals was obtained for his guidance.

Not very long ago, when there were rumours of war, a new photographic wagon was to be completed in its equipment, and the sealed patterns were produced to govern the supply. All the chemicals had suffered no deterioration except one, and that was the pyroxyline. Had the new supply been obtained according to the sealed patterns, photography would have had but an indifferent issue. The bottle containing the pyroxyline was filled with dense red fumes, and had evidently begun to decompose, giving off nitrous acid fumes. The collodion made with it in this decomposing state would evidently not be up to its normal quality. I was asked by an officer if, like explosive gun-cotton, it could not be kept wet, or even immersed in water. Fortunately, I was able to give him an assurance that it might not, for I had vivid recollections of a large supply of pyroxyline which had come back from the Transit of Venus expeditions, and had been kept in water, that had gone on decomposing for a couple of years, till it became nearly insoluble in the usual solvents. All photographers are aware that frequently when adding colourless, or nearly colourless, iodizers to plain collodion, there is, in some cases, an immediate production of free iodine, which may, or may not, be subsequently absorbed. The cause of this is often laid to the door of the solvents, and it may be so; though I doubt not that the impurity of the solvents (for they must be acid to liberate free iodine) has often been caused by the decomposition of the pyroxyline and the liberation of the nitrous acid. Of one thing, however, I am certain, and that is, that pyroxyline, after being dissolved up, is still liable to go on decomposing if nothing but ordinary solvents be used. I do not intend to imply that a developed film will decompose; but that a film which is not developed may go on decomposing and liberating nitrous acid, if the original pyroxyline has a tendency to decompose. In a washed emulsion plate without any preservative, how does the matter stand? It stands thus, that if a film has been exposed to light in the camera the image will fade, for I have already shown, in a previous paper, that this nitrous acid *destroys the photographic image*. I will recount one experience of this. I prepared several

emulsion plates without preservative, and during my absence from town in October, and about a week before my return, they were exposed to the spectrum. On coming back I immediately tried to develop them, but found that the image had entirely disappeared; there was not a trace of it. On seeking for the cause, I could not lay it to oxydation, as I often had kept emulsion plates for a much longer period, and found that they were always capable of development. In examining my pyroxyline I found that it was in a state of decomposition, as evidenced by the smell of the nitrous fumes. I exposed the whole of the cotton to the air till no trace of the smell remained, then replaced it in a clean bottle and placed it in a test tube containing a solution of potassium iodide. In a couple of hours the presence of the iodine was abundantly proved, showing that the decomposition was still going on. An exposure of a plate inside the bottle for twenty seconds nearly obliterated the photographic image. Here, apparently, was the cause. Another experiment seemed incumbent. A plate was coated with the emulsion, dried, and placed in a pure atmosphere in contact with starch paper; after a short interval, iodine from the potassium iodide was liberated. Here, then, we have one cause of the fading of the photographic image by the use of impure pyroxyline.

Now, I do not wish to insinuate that the pyroxyline had been improperly washed; I believe it had been well washed; but it happened, as is the case with the explosive gun-cotton, that spontaneous decomposition had set up, and by—for want of a better term I will call—catalectic action the whole mass was in a state of change.

It is curious how one experiment suggests others. After I had carried out these, it occurred to me that it was quite possible to cure the evil, and even utilise the action. I will describe my experiments, which can be repeated by anybody to be confirmed or disproved.

The question I asked myself was, On what does sensitive-ness depend? It must depend on the ready absorption of the liberated halogen, and probably on nothing else. It then struck me, if I were right in my surmise, that in such a case an excess of an alkaline or monad bromide in an emulsion should not diminish sensitiveness, or rather, I should say, should not prevent a photographic image being formed which is capable of development, provided I supplied the film with some bromine absorbent. What so natural as a nitrite or sulphite of an alkali? The experiment was carried out in my dreams one night, and really executed the next day, and with perfect success in both cases. Fancy and reality went, for a wonder, hand in hand, and did not contradict each other. In these two plates I can show you the result of the experiments. I had a simply washed emulsion prepared with an excess of silver nitrate. I took some of it, and added to each ounce three grains of potassium bromide. I coated the plates with it, and over one half I poured a dilute solution of potassium nitrite in alcohol, but carefully avoided returning any to the cup, in order to prevent the bromide being carried off the plate, and thus affecting the result. The film was then dried and exposed, and developed with ferrous oxalate. Now note the result: the part over which the bromide alone existed is absolutely devoid of any trace of an image; but where the nitrite had obtained a footing, along with it the image is developed perfectly, and I may say, that it came out rapidly. With sodium sulphite the same result was obtained. Now, as to sensitiveness, I wish to speak more guardedly. I do not think that the presence of free soluble alkaline bromide does affect rapidly. Here I have a plate, the whole of one surface of which was coated with ordinary emulsion, one-third was dipped in a solution of potassium bromide alone, another third in a solution of potassium bromide and potassium nitrite, and was then dried. Exposed behind a negative, it will be seen that the detail is equally well defined on that part of the film on which the soluble bromide and the nitrite was dried, as on that in which the film remained in its original state; whilst on that part to which

* Read before the Photographic Society of Great Britain.

the bromide alone had been applied, the image was exceedingly feeble, and almost refused to develop. I would have you also remark that the densities of the first two portions are almost identical—in fact, it is hard to see the line of separation between them.

(To be continued.)

ON AN INSTANTANEOUS SHUTTER.

BY COL. STUART WORTLEY.*

In showing my instantaneous shutter, I may remark that these two specimens are unnecessarily long, owing to being made to cover certain extra large lenses. In all ordinary cases they do not project beyond the sides of the camera. The larger one is used on a camera fifteen by thirteen, the smaller on one seven by seven. I find it necessary to use an instantaneous shutter with the highly sensitive gelatine plates, and I originally used what is known as a drop or guillotine shutter; but in using it I found that the sky was much over-exposed, and it struck me to avoid this by designing a shutter to work horizontally. I am thus enabled to use two butterfly wings, with which I decrease the size of the exposing slit at pleasure, and with the great advantage of so shaping the opening as to give a far longer exposure to the foreground than to the sky. Thus in this picture which I show, you will see that the exceedingly short exposure it received has prevented any of the halation or blocking of the lights so often seen in cloud pictures, and that the clouds round the sun, and the sun itself, are perfectly clear and distinct.

You will notice that the shutter is quite independent of the camera—it can be made and fitted to any camera by merely sending the front to the maker, it having a false one, and can be taken on and off in an instant.

Mr. Collins, of 56, Cochrane Street, St. John's Wood, has made these for me to my designs, and I have to thank him for the care bestowed on their get-up.

I may here, for a moment, point out a curious thing in carbon printing. You will see a number of clear specks. These are due to the transparency, while wet, being caught by the frost, the little holes appearing after it was thawed.

One point regarding the development of dry plates. I have often pointed out, in papers read before the Society and in other writings, the necessity for a minimum quantity of pyrogallie acid being used at first. If this is done you get a delicate and very perfect negative. But if you use strong pyro at first, you injure the negative. Use very very strong ammonia and very little pyro, then add pyro afterwards, according to the density you require. I am also anxious again to call attention to the absolute necessity of using a sufficiently non-actinic light in preparing and developing highly sensitive dry plates.

I here show a piece of deep ruby glass. I have printed in twelve minutes, by the light of a paraffin lamp, a perfect transparency through this piece of glass, and I do not know how to call your attention more forcibly to the advice given in the preceding paragraph.

COPYRIGHT IN PHOTOGRAPHS.

The following, referring to the clumsy construction of the present Art Copyright Act, appears in the *Times* :—

Sir,—If we are to have fresh legislation on this subject, let us hope we shall have something more reasonable than the language of 25 and 26 Vic., cap. 68, which, after (section 1) vesting copyright in works of art made or sold after that date in the author for his life and seven years after his death, goes on to say, "provided that when any printing or drawing or the negative of any photograph shall, for the first time after the passing of this Act, be sold or disposed of, or shall be made or executed for or on behalf of any other person for a good or a valuable consideration, the person so selling or disposing of or

making or executing the same shall not retain the copyright thereof, unless it be expressly reserved to him by agreement in writing signed at or before the time of such sale or disposition by the vendee or assignee of such painting or drawing or of such negative of a photograph, or by the person for or on whose behalf the same shall be so made or executed, but the copyright shall belong to the vendee or assignee . . . or the person for or on whose behalf the same shall have been so executed." Had the enactment stopped here, the matter would have been rational enough, but it goes on—"nor shall the vendee or assignee thereof be entitled to any such copyright unless at or before the time of such sale or disposition an agreement in writing, signed by the person so selling or disposing of the same, or by his agent duly authorized, shall have been made to that effect." Would it not have been simpler to say (what is said in effect by this circumlocution), "Unless at the time of sale of a painting, drawing, &c., an agreement is made in writing as to who is to have the copyright, vendor or purchaser, there shall not be any copyright at all?"—I am, sir, yours obediently,

JOHN CORYTON.

The Temple, January 16th.

The following letter subsequently appeared in the same journal :—

Sir,—the copyright question so frequently crops up in the *Times*, thereby evincing an unsettled affair, that it is hoped it may be finally disposed of next Session.

As a member of the Copyright Committee of the Society of Arts, at whose suggestion the late code was adopted (though that code was much curtailed by the law officers of the Crown), I write, having since assisted at the Antwerp Congress of 1877, where most nationalities were represented, and again in Paris last year, when the subject was very fully discussed, the committee, which was a very large one, composed of all nations, sitting each morning at the Louvre and in the afternoon at the Trocadero. This committee, which was at first presided over by the Minister of the Fine Arts (I need not tell you, never an artist), and after by M. Meissonnier, with M. Huard, of the Cour d'Appel, as secretary, has now made its report, which I believe may be purchased, and which should be studied before the Royal Copyright Commission's suggestions become law. As the only representative of Great Britain, I had to argue unsupported. The General Assembly unanimously ratified the proposition of the committee that works of arts should protect themselves—that the artist should lose nothing, there should be no registration or reservation of copyright at time of sale, the author's work requiring no signature or evidence other than itself, which I strongly maintained could be easily identified by experts. I dissented strongly against the prolongation of the term of artistic copyright to a hundred years! But as it was intended to benefit the artist's family, and took in the poor musician, I voted also for this, which, I believe, will become international French law. Most of the representatives have made reports to their Governments, and I have reason to believe the French Administration will communicate with ours upon the subject, if they have not already done so.—Yours, &c.,

Royal Institution of Great Britain.

JOHN LEIGHTON.

PHOTOGRAPHIC ENGRAVING.

BY CAPT. J. WATERHOUSE, B.S.C.*

Woodburytype Methods.—It has already been shown that in the Woodburytype process the photographic image is impressed into a soft metal plate by means of a relief in insoluble gelatine on a collodion support, and that instead of impressions being printed in ordinary printers' ink they are made in coloured gelatine. In such prints the gradation of shade is continuous, and there is no perceptible grain.

Mr. Woodbury has proposed an ingenious method for obtaining gelatine reliefs with a granular surface, so that, when impressed into soft metal, electrotypes in copper may be obtained from the latter, which will serve as printing-plates for printing with printers' ink in the copper-plate press, and yield superior results to those obtained by electrotyping immediately from the gelatine relief.

A plate of glass is waxed and coated with a thin film of

* Read before the Photographic Society of Great Britain.

* Continued from page 27.

collodion, and a mixture of gelatine and bichromate of potash, containing a quantity of fine emery, powdered glass, or charcoal, is poured over it and allowed to set. The gelatine film is then dried and taken from the glass, and the collodion side exposed beneath a negative. After a sufficient exposure, it is temporarily attached, on the collodion side, with india-rubber solution, to a sheet of glass, and washed in warm water.

The resulting granular image is then pressed into a sheet of soft metal by means of the hydraulic press. The soft metal plate has an electrotype made from it in copper, and another plate, subsequently covered with a coating of iron, is again made from this to serve as the printing plate, the first copper plate being kept as a reserve.

Mr. Woodbury also describes another method which in some respects resembles Geymet's, before described.

Paper is successively coated with three or more mixtures of gelatine, bichromate of potash, and some granular substance in different degrees of fineness—first with the coarsest, and lastly with the finest. When dry, the tissue is exposed under a negative, transferred under water to a finely polished plate of zinc or steel, then washed in warm water as usual, and when dry is ready for pressure into the soft metal block. In this case the light tones are composed of the finest grains, and the shadows of the coarsest.

M. Rousselon, the manager of Messrs. Goupil's photographic works at Asnieres, near Paris, has obtained engraved plates with remarkably good half-tones by a process somewhat similar to the Woodbury-type, which is also largely worked by Messrs. Goupil. The peculiarity is in the grain, which is obtained by the addition to the sensitive mixture of gelatine and bichromate of some substance which has the property of causing the film to become granular under the influence of light, the granular effect being increased in proportion to the intensity of action of the light. The other operations are the same as in the first of Mr. Woodbury's processes just described. The details of this process are a secret, but it is said that the substance used for producing the grain is chloride of calcium.

I am not aware of either Woodbury's or Rousselon's processes being utilised for the reproduction of maps, but in certain cases they could, no doubt, be usefully employed. The only difficulty seems to be that an immensely powerful hydraulic press is required for large subjects.

Photo-mezzotint.—The Editor of the *British Journal* has lately suggested a process of photo-mezzotint engraving founded on the dusting-on or powder process, already alluded to. A polished steel plate is thickly coated with—

Saturated solution of bichromate of ammonia				
ammonia	5 drachms
Honey	3 "
Albumen	3 "
Water	1½ pint.

When the coating is thoroughly dry, the plate is exposed to light under a transparency. A large camel's hair brush is charged with a mixture of the two finest kinds of emery powder, and applied with a circular whisking motion all over the surface. The powder attaches itself to those parts of the plate on which the light has not acted, precisely in proportion to the amount of protection they have received, owing to the unaltered parts of the film attracting moisture and becoming tacky. The most tacky parts, forming the deep shadows of the picture, will attract the coarsest particles of the emery, the finer parts will take finer emery, and the highest lights will take none at all. When the picture is fully developed, it is placed face to face against a polished plate of softer metal, and passed between a pair of rollers, so that the emery powder image may be indented into the polished metal. The plate is then burnished in parts by a skilled engraver, and when the desired result is

obtained, is printed in the usual way in the copper-plate press.

This process seems capable of rendering useful service in the reproduction of maps.

Scamoni's Method.—The last method is that recommended by Herr C. Scamoni, of the Imperial Russian State-Paper Office, and is fully described in his "Handbuch der Heliographie," already referred to. The results are exceedingly good, but the process is only suitable for line work.

Herr Scamoni, having obtained a suitable negative of a drawing or other line subject, makes a positive copy of it in the camera by the wet collodion process, and after fixing, treats this positive with various successive intensifying solutions, so as to give it a very sensible relief. After drying the plate is varnished with a thin varnish and coated with fine plumbago, after which it is electrotyped in the usual way.

In the specimens I have seen of this process the lines are exceedingly sharp and fine, and it would seem well adapted for map-work.

A photo-mechanical process has lately been introduced by Messrs. Aubel and Kaiser, of Lindenhöhe, near Cologne, and called "Aubeldruck." The results for line-work are very superior, but the process is a secret. It is believed to consist in some method of etching a glass negative, so that prints may be obtained direct from the glass surface or by transfer to stone.

In all cases where the printing-plates are obtained by electro-deposition of copper, and many copies are required, it is necessary to protect the engraved surface of the plate with a coating of iron by the process known as 'acierage,' or steel facing. This enables a very large number of copies to be printed without deterioration of the plate, and the coating can easily be removed and renewed whenever required. Details will be found in Ure's "Dictionary of Arts, Manufactures, and Mines," article Engraving.

(To be continued.)

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

In his next chapter the author proceeds briefly to describe the properties of isinglass and of agar-agar. With respect to the former of these, he remarks it can only be obtained of very unequal, and generally of very inferior, quality; it is therefore much better always to use gelatine. For collotypes, also, isinglass cannot be used, as it is soon crushed under the press.

A vegetable gelatine, the product of a sea-weed—agar-agar—is also found in the market. This substance is not so soluble as gelatine; a jelly made with half per cent. of agar-agar is firmer than one made with four per cent. of French gelatine, and can be heated to from 30° to 50° C. before it begins to melt. It is not sticky, and is free from nitrogen. For collotype purposes the employment of this vegetable gelatine is attended with difficulties on account of its insolubility in anything but very hot water; but it may be used as an adjunct to ordinary gelatine, to which it gives greater firmness. More especially in tropical climates its application in this way for carbon printing and the collotype process has been recommended.

The author now proceeds to describe the behaviour of a quite different kind of substance—sugar—with the chromates. He first explains the action of light on a mixture of cauc-sugar with chromic acid and the different chromates of the alkalies. Chromic acid oxidizes sugar very rapidly, turning it brown even in the dark. Potassium bichromate mixed with a syrup of sugar can remain for

* Continued from page 26.

weeks without alteration, if kept in the dark, and when exposed to the light it turns brown very slowly. The mixture with sugar is in every respect much less sensitive to light than with gelatine. Chromated sugar that has been thus affected has not lost its solubility; it must be exposed to light for some weeks before it is so far decomposed as to give chromium chromate in excess. The latter, then placed in water, remains undissolved, so that it cannot be asserted that sugar is rendered insoluble in water by the bichromate; but the action of light causes it to lose its hygroscopic properties, for in the parts that have been exposed to light products of oxidation and salts of chromium are formed, which have no tendency to absorb water.

In order to determine the chemical action that light produces on a mixture of sugar and potassium bichromate, the author undertook a series of elaborate experiments. Concentrated and saturated solutions of the two substances were mixed and evaporated at the ordinary atmospheric temperature, and then exposed to direct and full sunlight for between three and four weeks. During this time the mass was often stirred and comminuted, and at the end of it had turned of a brownish black colour. A portion of it dissolved in water, and acidulated with acetic acid, was tested with calcium chloride for oxalic acid, but without result. From another similarly prepared portion the chromic acid was removed by barium nitrate, the filtrate neutralized with ammonia, reduced by evaporation, and mixed with lead nitrate. Again no precipitate was produced, proving the absence of saccharic acid.

Having shown that the chromated sugar does not, under the action of light, form either oxalic or saccharic acids, the author next adopted another method of proof. He took another portion of the substance, precipitated the chromic acid with baryta water, and distilled the filtrate with dilute sulphuric acid. A dark and acid liquid distilled over abundantly, possessing the well known smell of formic acid. This liquid was then saturated with lead carbonate, and after filtering and evaporating it yielded brilliant and transparent prismatic crystals, insoluble in spirits of wine. The amount of lead in these crystals, determined by a quantitative analysis, gave precisely the same results as lead formate. We conclude, therefore, that sugar and potassium bichromate, when acted on by light, produce formic acid. It has long been known to chemists that this acid is one of the products from the action of potassium bichromate and sulphuric acid on various organic bodies under the influence of heat. Now, therefore, we know that mixtures of the chromates with sugar, gelatine, gum, &c., when exposed to the light, produce a double basic chromate and formate of chromium, and the chromium oxide, as we have seen in the case of gelatine, gives rise to secondary phenomena, such as insolubility.

It has been already mentioned that the chromated sugar, when acted on by light, loses some of its hygroscopic properties, and more especially is this the case with grape sugar. Advantage is taken of this property in the dusting-on process. A plate is coated with a mixture of gum and sugar with potassium chromate, and exposed to the light. If now the image thus formed be breathed on and dusted with powdered graphite, it will be found that the powder adheres only to those parts that were protected from light. For this purpose grape sugar, as has been above stated, is preferable to cane sugar; honey and glycerine can also be employed with advantage, but neither gives such good results as grape sugar. The phenomenon is explained on the theory that the sugar, or grape sugar, is reduced by oxidation to formic acid, which, with the chromic oxide produced at the same time, forms a basic and weakly hygroscopic salt. It must be noticed, however, that the exposed parts of the chromated sugar film have not lost their capability of attracting moisture altogether, but that they possess that capability in a less degree

than the parts that have not been altered under the influence of light.

The monochromate of potassium mixed with sugar may be exposed for months to the light without undergoing any alteration worthy of notice. We have here the same want of sensitiveness as in the case of gelatine. The double chromate of potassium and ammonium gives with sugar very sensitive and durable films, which, however, are not in use. Chromated sugar may be used alone in the dusting-on process, and pictures obtained on it, but they are very liable to injury, and the process itself is uncertain. Sugar is often added to the gelatine in both the collotype and carbon processes, but for the former purpose its use is not recommended, as it makes the gelatine soft, and liable to crushing under mechanical pressure.

In photo-electrotypy the addition of sugar is strongly recommended by the author, on account of its promoting the solubility in hot water of the gelatine not acted on by light. Its operation in this way, however, is not photographic, but mechanical, for the influence of light on the chromated gelatine has ceased before that on the chromated sugar comes into play. Its use in the carbon process has also been advocated, because of its giving the paper a certain suppleness and pliability, but as the sugar dissolves in the chromate bath when the paper is sensitized, it promotes the decomposition of the latter. According to Johnson, when sugar is contained in the gelatine film the carbon paper is more easily acted on by a dry or a moist atmosphere; in dry weather it turns brittle, and sometimes the gelatine film becomes so soluble as to dissolve in the chromate bath, even at ordinary temperatures. For these reasons it has been proposed to substitute soap for sugar; on the other hand, Cooper advocates the addition of glycerine. The author, however, remarks that sugar dissolves with difficulty in the alcoholic chromate baths that are now so commonly used, whereas soap is highly soluble in the same, so that pollution of the bath is more to be feared in the latter case. Waterhouse also recommends the addition of soap to the film in collotype printing.

(To be continued.)

SPECTRUM PHOTOGRAPHY.

The following appears in the *Times* in continuation of the correspondence we published last week:—

SIR,—It has been said by somebody that if people who take opposite sides in a discussion were to nodorstand distinctly what they were going to oppose, half the discussion would be avoided. When my learned and gallant friend Captain Abney takes exception to my strictures on a statement in the *Times* relative to Vogel's theory of stained films, I am at a loss what to reply until I know whether he means to say that stained photo-sensitive films acquire a susceptibility to lines in the spectrum according to their imparted tint (dye)—i.e., a film stained red registers red lines; one green the green lines, &c.—or not. If he maintains a relation of law between the colour of the dye and the lines it will photograph, he affirms Vogel's theory, which I maintain to be without foundation in principle or practice; if, as I read his note to the *Times*, he disputes Vogel's theory, we are at one, and there can be no discussion on that ground. It has long been shown that various organic and non-organic substances are susceptible in various degrees to the different colours of the spectrum; but definite chromatic correspondence between the two classes of variation is, so far as I have been able to learn, entirely contra-indicated by the experiments hitherto made.

The subject is one which will not interest largely the readers of the *Times*, but it would be of the highest importance to the science of photography if Vogel's theory were shown to be valid, as it must revolutionize the practice of photography. It is, in my opinion, on the contrary, one of those things odious to lovers of sound induction—a theory shaped out of a conjecture, with facts tortured to testify to it, and the multitude of opposing facts put out of sight.—Yours truly,

W. J. STILLMAN.

THE PHOTOGRAPHIC USE OF OXALATE OF IRON.

As a rule we do not think it expedient to intervene in discussions maintained in our pages by correspondents. But there are times when controversy may be shortened by the mention of a few facts which seem to be lost sight of by the disputants on both sides. The fact that certain salts of iron were reduced by light to proto-salts was known at a very early period, is tolerably clear, and it was also known that the oxalate was of this number. So far as any evidence exists, however, this reaction was only made available in producing images of platinum, silver, or gold.

The observation that light exercised a reducing influence on peroxalate of iron appears to have been noted by Döbereiner earlier than Hunt or Herschel. But the question arises as to the first process for producing pictures. Dr. Emerson Reynolds claimed this in a paper read before the Dublin Chemical Society in December 1861. He defended his claim of having introduced a "new process," on the ground that whilst the principles upon which it was based were known earlier, they had not been applied and formulated into a process. Dr. Phipson then pointed out that he had formulated a process nearly twelve months earlier than Dr. Reynolds, which he announced first in the *Moniteur de la Photographie*, and subsequently described in full in the *Photographic News*, January 14th, 1862. An important distinction here occurs, however. Dr. Reynolds' picture really embodied the old principles, and his picture consisted of reduced silver, whilst that of Dr. Phipson was an image of iron. So far as evidence exists, the latter was the first print produced by oxalate of iron, and without the aid of silver, gold, or platinum. It is worth noting, in connection with this subject, in the *Photographic News* of September 20th, 1861, Harry Napier Draper (the son, we believe, of Dr. Draper) describes some experiments with paper floated upon a solution of prussian blue in a saturated solution of oxalate of ammonia, dried, and exposed under a negative. The paper acquires a faint blue colouration. Washed in water, and treated with hydrochloric acid, the impression becomes intense. After washing and drying, and exposing to light, the image fades, but is restored in darkness. He had not time for further experiment, but suggests that a black or dark brown image of iron might be formed, and a new mode of printing obtained. We, with Captain Abney, would not doubt Dr. Draper's word, but in stating that he has produced photographs by aid of the oxalate of iron, he distinctly states that the images were formed in silver and gold.

PAYMENT IN ADVANCE.

PAYMENT in advance, it is manifest, is an imperative condition of many kinds of business. In relation to many matters involving small sums already fixed at their minimum rates, if their cost and trouble of booking, of subsequent making out of accounts and applying for them, the giving of credit included in all this, and the risk of loss were added, they would constitute a prohibitory tax on the business. Hence payment in advance has come to be a necessary condition of many trades. But this prepayment involves in its turn many inconveniences and risks, and is easily made available by dishonest adventurers as a means of swindling the trustful and unwary. Attractive advertisements, offering enticing bargains of various kinds, for comparatively small sums in stamps, frequently appear. Sometimes such offers are *bona fide*, but they are not unfrequently partially or completely swindles. In some cases there is no intention of supplying anything for the amounts sent. In other cases the article sent, or the work done, is so inferior, that unless payment had been secured beforehand, little chance would exist of obtaining it afterwards. Some cases—happily, not many—have been brought under our attention of late, in which announcements appearing in the advertising columns of the *PHOTOGRAPHIC NEWS*, demanding payment in advance for enlarging, colouring, &c., have issued in disappointment. In some cases, money and negatives have been sent, and no further communication has been obtained. In others, work has been sent in return which has been altogether unsatisfactory and useless. In such cases we are not unfrequently appealed to for further information, and occasionally the disappointed applicants imply that some sort of responsibility rests on the journal in which such advertisements appear. Of course, the fallacy of such a notion needs no serious disavowal. It is impossible that the managers of a journal can have responsibility for or knowledge of advertisers whose announcements are brought to the office, and their insertion paid for in advance.

Some weeks ago, we published a letter written by Mr. C. E. Elliott, cautioning provincial photographers against dishonest adventurers requiring payment in advance for goods announced. We print this week another letter from the same gentleman regretting that his last letter has been misconstrued by some, who have been induced to refuse prepayment to respectable established firms, for goods where the terms charged involved the necessity of such prepayment. Mr. Elliott explains that he did not, of course, suggest that photographers should in all cases refuse to pay in advance; but simply that they should make proper enquiries as to the standing and trustworthiness of dealers making such demands. Practically, Mr. Elliott suggested that common sense and common prudence should be used. Established houses of business are usually well-known, and references can be obtained, so that little risk can exist in forwarding money to them for a purchase; whilst individuals residing in the country, being unknown, can scarcely expect to receive goods without cash or satisfactory references. A tempting advertisement offering to supply some great bargain, issued by an unknown person, should be the subject of careful enquiry before money is sent. And in all cases it is better to build up mutual trust by commencing with small transactions, so that any possible failure in satisfaction may not involve serious consequences. In many cases prepayment is necessary, but with care in enquiry and obtaining references, no trouble or loss need ensue.

THE FORTHCOMING DRY-PLATE COMPETITION.

A QUESTION having arisen regarding the forthcoming dry plate competition as to one point left doubtful in the published condition, the following correspondence will

explain the uncertainty and its solution. Mr. Henry Cooper writes to us as follows:—

"DEAR SIR,—Although not intending to compete for the Paget prize, there is one point in the conditions which I should like to see cleared up. Three plates ready for exposure, 8½ inches by 6½ inches, are to be sent in, and two or more negatives. The question is, are the latter to be of fixed size, the same as the plates, or may they be of any dimensions?—Yours truly,
H. COOPER."

We at once forwarded Mr. Cooper's note to the committee appointed by the Council of the Photographic Society to make arrangements. Mr. Sebastian Davis, on behalf of the committee, wrote as follows:—

"In accordance with Mr. Glaisher's request, I reply to Mr. H. Cooper's query with respect to the size of the finished negatives to be sent in competition for the Paget dry-plate prize. The finished negatives may be of any size, as the printed conditions only specify 8½ inches by 6½ inches for the unexposed plates. The object is that the committee may be able to test all the unexposed plates with a given lens in the same camera, whereas the finished negatives are simply required as an evidence of the quality of the pictures produced by the photographer himself by the process described.—With kind regards, yours faithfully,
T. SEBASTIAN DAVIS."

We hope that the opening sentence of Mr. Cooper's note does not imply a settled resolution, as we should regret to see a dry-plate man of such experience and skill as Mr. Cooper refrain from such an interesting and important competition.

IMITATION PORCELAIN TRANSPARENCIES.

WE have received from a correspondent, Mr. W. J. Anckorn, a pretty example of a simple mode of producing transparencies imitating porcelain or opal glass. The transparency is produced on plain glass and backed with albumenized paper, and, when glazed and framed or bound, is not easily distinguished from porcelain. Mr. Anckorn finds the production of such things a pleasant photographic occupation, which may be taken in hand during long evenings, daylight not being necessary. Here is his account of his mode of proceeding:—

"The first thing necessary to be done is to albumenize the plate, and when dry sensitize in the ordinary way. The albumenizing of the plate is to keep the collodion from breaking when taking the plate from the negative. After the transparency is printed and developed, it must be redeveloped with pyrogallol and glacial acetic acid. After that is finished, dried, and varnished, the next thing it will require is to be backed up with albumenized paper, and a glass the same size fixed at the back of the paper, and then bound all round.

"If you look at the picture sent, you will see by looking at it before the eyes it is almost like china. Portraits look first-class done this way, and we shall see a good many this summer, I hope."

A RELIABLE DRY-PLATE PROCESS.

BY HENRY COOPER.

IN last number of the PHOTOGRAPHIC NEWS a correspondent signing "Servant," appeals to me to give sundry items of information in connection with my recently published "reliable" dry process.

He has failed to obtain syrupy lactate of ammonia, and as many others may be glad to know where they can procure a good sample, I have pleasure in mentioning the fact that I have always found the lactate supplied by Messrs. Hopkins and Williams to be most excellent. Their address is, Cross Street, Hatton Garden, E.C.

Your correspondent then says:—"Next as to the emul-

sion. Seeing that the plates are washed and preserved in the ordinary way, would it not be as well to use the emulsion when ripe instead of washing and drying it; or is there any specific reason for the washing?"

In reply, I may briefly call his attention to one or two points. The primary object in washing the emulsion is to arrest the ripening process, if I may so term it, at the proper moment, and thus secure a large bulk of emulsion which will remain without further change. With some emulsions there would be no objection to using it for the preparation of plates as soon as ripe, provided the whole of it were used up at the time; and although I cannot recommend the method with my emulsion (not having tried it), I see no reason why it should not succeed, provided due care is taken to add some nitric acid to the first wash water, and then to soak the plates for some time in pure water, and finally rinse thoroughly before coating with albumen. I should, however, be inclined to imagine the film would have a tendency to blister and slip during the washing, on account of the large quantity of nitric acid which must be used. On the whole, I should advise "Servant" to carry out the process in its integrity.

I have left his first question until last. He says:—"1st. With regard to exposure. Of course it would be impossible to give any definite time, but some data might be given to go upon. On a fine day in May, for instance, to take a fine landscape with a No. 6 Portable Symmetrical lens with middle size stop, what time would be about right?"

It is almost impossible to give any *reliable* data for exposure, or even to state any degree of comparative sensitiveness which shall prove of practical use. The old-fashioned plan of stating that a certain process was so many times slower than the *wet* was a most fallacious one, considering the enormous variation in the sensibility of wet collodion plates as prepared by different individuals, and was also doubly misleading, unless the axiom be borne in mind that, as the strength of light *diminishes*, so does the difference of time required by any two plates of various degrees of sensitiveness *increase*, to the marked disadvantage of the less sensitive plate."

To explain my meaning more fully, I may state a case in point. Working a certain dry process against my wet collodion, I found the plates by the former required half as long again as the latter in a good light and with an open subject; but with a more feeble light, or for close subjects, the dry plate needed an exposure of five or six times the other, until at last a point was reached where even an exposure of one hundred times as much would fail to give an equal result. The rule just given explains a fact which has caused some astonishment among photographers. I refer to the statement that the newest and most sensitive gelatine plates, which in a good light may be five times as sensitive as a good average wet plate, require in a dull light an exposure only one-thirtieth or less what the wet plate would need.

This is a point which I tested very thoroughly some months ago. On a gelatine plate, which in a bright light was twice as sensitive as the standard process, I was able to obtain a fully-exposed negative with a moderate exposure, under conditions where the ordinary plate failed to give even a decent result with an exposure fifty times as long.

I mention these facts now to show your correspondent how unsatisfactory it is to attempt to give the data he requires.

I am always ready to help others to the utmost of my means, and I give a few jottings from my note-book in reference to the exposures of the pictures I exhibited last autumn, and trust these may prove sufficient guide for "Servant." I must, however, remark that the best way to arrive at an idea of the sensitiveness of plates prepared according to my method is to make a few, and expose one

or two as tests. Also I must call the attention of all those who propose trying my method to the statement I made that, by merely altering the proportion of pyroxyline in the emulsion, a really wonderful difference in the sensitiveness of the finished plates was made.

I hope to have more to say on this point before long, but must forbear writing about it now, and will conclude this letter with the jottings from my book.

"July 15th. View from Kuarsborough Bridge. Open subject. Bright light, 12.15 p.m. No. 7 Portable Symmetrical; largest stop. Twenty seconds.

"July 31st. Fountains Abbey. No great contrasts. Good light, 11.45 a.m. No. 7 Port. Sym.; stop No. 2. Eighty seconds.

"May 9th. Ivybridge; dark river bit, with bridge and foliage. Good light, 2.45 p.m. No. 5 Port. Sym.; largest stop. Three and a-half minutes.

"May 9th. River bit; trees against the light and near to the camera: dark foreground. Hard, bright light, 3.30 p.m. No. 7 Port. Sym.; largest stop. Five minutes.

"July 31st. Near Fountains Abbey. Open bright bit, with much distance, 10.30 a.m. No. 7 Port. Sym.; largest stop. Two seconds."

The first four entries refer to pictures which, perhaps, "Servant" may have seen at the last Exhibition.

THE CAMERA AND PLEASURE.

BY JAMES CHINN.

I READ in the columns of the NEWS, with feelings of sympathy, an article on the subject of unsteadiness of pocket-cameras. Now, mine is not a pocket-camera, but about the size of a very small portmanteau, measuring 16 in. by 10 by 10, and weighing 23 pounds. This may be considered heavy, but there is no changing box, but bellows-body camera, square cabinet size, the slides made to hold the plate vertically or horizontally. There are twelve of these standing, side by side, in the box, and the camera at one end. Alongside the slides is a square piece of wood, the top of the stand to which the legs are attached, with thumb-screws, and secures perfect rigidity. When travelling, I place two rubber bands around the legs; they are easily carried. Mine are 1½ inch by 1 inch at top, and lean down 18 inches, and 1 inch by 1 inch at the bottom. On the slides I place a good-sized focussing-cloth, and with the slides charged with coffee plates, all you have to do is to pitch your camera, focus, take up a slide, place it in the camera, expose, replace it in your box, and at your leisure be satisfied with developing something worth calling a negative.

If the above were made by an experienced hand, and of mahogany, it would be considerably smaller and much lighter, and still retain its rigidity. I made mine of New Zealand timber.

Blenheim, New Zealand.

A METHOD OF FIXING,

Upon Wood, Glass, or Porcelain, any Photograph, whether printed in pigments, gelatine, or silver; also of Destroying the Paper, or other Basis upon which the print rested, so as to obtain a clear image on the wood, porcelain, or glass.

BY ROGER LAURENT.

To do this, I employ the white picture varnish of MM. Soehnée frères. In the first place, the engraving or photographic print of whatever kind, is put into water for twelve hours, so that the varnish, when applied, may not penetrate it.

1. The picture varnish is poured upon a warmed glass plate in the same way as you collodionize. As this varnish does not dry immediately, there is time to perform the next operation.

2. The print is taken out of the water (without bubbles)

and laid upon a glass plate (face upwards). A sheet of blotting-paper is pressed upon the print to remove the superfluous water. In this condition, some of the same varnish is poured on like collodion. Then, care being taken to prevent bubbles, this varnished image is applied (face downwards) to the previously varnished plate. By means of blotting-paper, the image is pressed firmly down.

3. It is allowed to dry for three hours.

4. With the finger, or a piece of rag, or a sponge, you moisten and rub the paper backing until it is removed and the image begins to appear, taking care not to injure the latter.

5. As soon as the image appears clean and sharp, it is dried and covered with photographic varnish. Acidulated water will be found best for rubbing away the paper backing. It is a work of considerable patience.

Correspondence.

PAYMENT IN ADVANCE.

SIR,—It is a most difficult matter to steer clear for the interest of all.

The letter I addressed you some few weeks ago has been misconstrued, and some most respectable and trustworthy advertisers have complained that my letter has been the means of injuring them, as parties have refused to send their money till they have received the goods.

I did not intend for a moment to intimate that photographers should not send their money in advance, but only to make some inquiries, if they did not know the house, before thus sending.—Yours truly,

C. E. ELLIOTT.

PHOTOGRAPHY BY MEANS OF OXALATE OF IRON.

SIR,—The note you have been pleased to add to my former communication induces me to ask permission to say a few more words on the above subject. I am afraid that, in writing in haste, I did not state enough to show that I was justified in doubting the statement of "Historicus" as to Dr. Phipson being the first to obtain images by means of the oxalate of iron. I think by giving the manner in which Hunt relates the discoveries of the properties of the silver salts, it will be seen, by comparison with the list of iron salts already given in my last, that he makes distinction between the discovery of the photogenic and photographic properties in a way that justifies the assumption that he intends no such distinction to be understood in the case of iron salts. Thus, in the historical chapter already quoted, I find

Silver, nitrate of	Ritter	... 1801
" "	(photographically employed)	Wedgwood and Davy	... 1802
" "	with organic matter...	Herschel	... 1839
" "	with salts of lead ...	J. F. Herschel	1839
" chloride of	C. W. Scheele	1777
" "	(photographically employed)	Wedgwood	... 1802
" "	employed)	Talbot	... 1839
" "	darkened and by-} drieric salts	Fife and Lassaigne	... 1839
" "	iodide of (photographically used) ...	Herschel	... 1840
" "	used) ...	Ryan	... 1840

It will be seen by this short quotation that Hunt has not lost sight of the distinctions to which you, Mr. Editor, have called attention; and I may ask, would not the person who claims to have been the discoverer of the properties of so many iron salts have made the same distinction in his historical list if there was any such distinction to be inferred? In fact, the work from which I quote gives formulæ in which many of the iron salts of which Hunt was the author (photographically) are used, e.g., the protosulphate, muriate, iodide, &c.; and it still appears to me

that "Historicus" is too positive in his statements. I submit that the most he can assert, without doubt, is that Dr. Phipson was the first, *within his knowledge*, that produced images by means of the oxalate of iron.—I am, sir, yours respectfully,
B. L.

SIR,—I have followed with much interest the discussion between my friend "Historicus" and Capt. Abney, as to the production of the first photograph by oxalate of iron. I published my process for producing a photographic picture by ferric oxalate in the year 1861; it appeared in the *Moniteur de la Photographie*, and subsequently in the PHOTOGRAPHIC NEWS, the *Technologist*, and in several other journals, both at home and abroad, under the title of "A New Process of Photography Without Silver." The proofs resembled silver prints.

When Capt. Abney shall have shown that either Dr. Draper or Mr. Hunt ever published a similar process before mine appeared, I shall be happy to yield my priority. At present he has not done so.—I am, sir, yours faithfully,
London, January 20. T. L. PHIPSON, Pn D., F.C.S.

PS.—We all know that Herschel made use of the tartrates and citrates of iron, but not the oxalate; neither had his process any resemblance to mine, as my prints were imitations of silver prints fixed by hyposulphite of soda.

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

SIR,—In consequence of the personalities contained in Signor Lombardi's letter of the 18th inst., I claim your permission to reply.

My contention with the Luxograph Apparatus Company is, that in spite of my refusal to order an apparatus from them, or to give them a testimonial, they published one written by Signor Lombardi, a member of this firm, which, as far as my name is concerned, is perfectly false; and Signor Lombardi, knowing all the facts of the case, has the assurance to justify himself and his Company.

Some years ago, wishing to give up photography as a business, I put an advertisement in your journal, stating my intention. In consequence, Signor Lombardi called on me. After a most grandiloquent introduction of himself, he told me the most amazing anecdotes of his mode of creating business. He boasted that there was not a man living who had his power of saying or doing *anything* to promote business, and finally he proposed to place his son, a young man who appeared to be about sixteen, but who may have been twenty years of age, with me as my partner! Treating the matter as a joke, I said, "What is the amount of his capital?" His reply was, "The clothes in which he stands upright, the valuable possession of my illustrious name, my mighty power of 'running' sitters in, and my enormous and exclusive interest in that excellent and voracious paper the *Daily Telegraph*." This proposal was received with excessive laughter. I certainly complimented him on his "great commercial abilities." But I added that rather than imitate his example, I would prefer to sweep a crossing. This was received as a high and graceful compliment by Signor Lombardi.

I do not expect this statement to be believed by anyone unacquainted with Signor Lombardi. Those who know him will, I am assured, give it implicit credence. All who know his work and mine will admit that it would be as reasonable to expect fire and water to unite harmoniously, as to expect his work and mine to assimilate. His assertion that I wished to form the firm of Lombardi and Faulkner is an example of his power of saying anything to carry his point.

In answer to his sneers about my plan of producing graduated backgrounds, allow me to say, that at his request I supplied him with four pounds of carefully prepared erayon, in four tones of colour, and a clothes brush (that being the best form of brush for the purpose), and ample printed instructions. Had these materials been used with ordinary

skill, Signor Lombardi's photographs would have gained in effect; as it was, he lacked the necessary talent to use them, and this deficiency I could not, unfortunately, supply. Signor Lombardi has described the above materials as "a bit of chalk—a shoe brush," a striking instance of his power of truthful description.

I suppose I ought to feel flattered that so successful a man of business as Signor Lombardi should have allowed himself to be so strongly influenced by my remarks that he was induced to purchase from his own firm three complete sets of apparatus, or, to use his own words, "to go in deep."

Apart from my own feelings on the subject, I thought it was due to the character of your journal to inform you of the falsity of the "Luxograph Testimonial."—I am, sir, your obedient servant,
ROBERT FAULKNER.

[The correspondence on this subject must cease here.—Ed.]

CADETT'S SHUTTER-FOCUSSING.

DEAR SIR,—If your correspondents just bore a hole in the camera-stand, any part most convenient, and when they wish to focus, just squeeze the pear, double the tube near it, and push the doubled part into the hole, they will find the shutter open. When all is ready, the act of withdrawing the pear closes the shutter. Or, tie a small india-rubber ring (such as used for umbrellas) on to the tube loosely, and when you wish to focus, squeeze the pear, double the tube, and slip the ring just over the bent part; you can then put the pear down anywhere. The act of picking it up straightens the tube, throws off the ring, and closes the shutter.—Truly yours,
W. H. M.

ELECTRIC LIGHT FOR COPYING.

DEAR SIR,—In a short article in the *Year-Book*, Captain Waterhouse calls attention to the electric light as a means of copying maps, plans, and drawings, and expresses an opinion that it would be of great service if used for that purpose. It is now nearly eleven years since I had the opportunity of testing the electric light in that direction; and although my experience with it was but limited, it was still sufficient to enable me to say that the electric light can be used for copying purposes with very great advantage. I enclose a photo-lithographic transfer made from a negative taken with the electric light at the time mentioned above. The negative is about one-third the diameter of the original print. It was taken with Dallmeyer's 10 by 12 triplet lens and the smallest stop; the time of exposure fifteen minutes, with the light six feet from the print. No attention was paid to the reflection or concentration of the light, and I have no doubt that if efficient means were adopted for doing so, the exposure would be reduced to half the time stated, and with the more recently invented rapid rectilinear I have no doubt three minutes would be sufficient with the smallest stop, which would be somewhat less than the average time with daylight.

I trust that the investigations at present going on may result in some modification such as will reduce both the first cost and the cost of the maintenance of the light, and thus place it within the reach of all who may wish to use it.—I remain, yours truly,
A. BORLAND.

35, Wellington Road, Stockport, January 18th.

[The transfer is excellent, and very sharp.—Ed.]

COL. STUART WORTLEY'S PAPER AT THE SOCIETY.

SIR,—I regret to say that I omitted to mention in my paper the distance at which a fully developed transparency was printed through the ruby glass I showed; the source of illumination being a paraffin lamp. The distance was ten feet.—I am, sir, yours, &c.,
H. STUART WORTLEY.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The usual monthly meeting was held in the Water Colour Gallery, Pall Mall, on the evening of Tuesday, the 14th, Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a previous meeting were read and confirmed.

The PRESIDENT intimated that the following members of Council would retire by rotation; eligible, however, for re-election, except the retiring Vice-President, who was not eligible for the same office during the coming year:—James Glaisher, F.R.S., President; Professor Stokes, F.R.S., Vice-President; W. Bedford; G. Wharton Simpson, M.A., F.S.A.; R. W. Thomas, F.C.S.; Lord Lindsay; J. T. Taylor*; Col. Stuart Wortley, members of Council: J. Spiller, F.C.S., Treasurer.

Captain ABNEY, F.R.S., read a paper "On the Fading of the Undeveloped Photographic Image, and on Soluble Bromides in Emulsions" (see page 33).

After some discussion Col. Wortley exhibited and described a new instantaneous shutter (see page 39).

In answer to a question from Mr. England, Col. Wortley said the size of the shutter was inconvenient for use close to the plate.

Mr. ENGLAND thought that the only method of having a perfect instantaneous shutter was by placing it close to the plate. He had designed one of this kind which was now in possession of Mr. Dallmeyer.

Mr. DALLMEYER had adapted the guillotine shutter of Mr. England to several cameras, and considered it theoretically to be constructed on the right principle, inasmuch as it allowed the full action of the lens on the plate: this was not the case in Colonel Wortley's method.

Mr. BLANCHARD thought that by using Mr. England's shutter there was an enormous gain. Without a doubt, the action was much more rapid than when the shutter was placed elsewhere.

Colonel WORTLEY did not want more rapidity. He had been able to obtain pictures fully exposed, the foreground of which was composed of dark rocks, and got all the detail he wanted. He admitted that for small pictures the shutter of Mr. England was advantageous, but for large sizes, such as 15 by 12, he did not think it was suitable.

Captain ABNEY remarked that the two best positions for a shutter were either in front of the plate, or where the diaphragm of the lens was placed. With respect to the ruby glass referred to by Colonel Wortley, he might say that he had never yet met with an example which did not let some blue light through. If the spectrum, after passing through ruby glass, were examined in a bright light, this would be distinctly detected. He had been obliged to discard ruby glass for this reason, and now only developed by candle or a feeble gas-light. He might mention that he had taken a transparency with blue emulsion under ruby glass in twelve seconds by the light of a paraffin lamp, instead of twelve minutes, the time of Colonel Wortley's picture. A good deal, so far as the exposure was concerned, depended upon the colour of the emulsion, and it was owing to this point not being sufficiently observed that failure sometimes resulted.

Mr. KENNETT inquired what Captain Abney used to shut out the light.

Captain ABNEY said that the globe of the lamp was coated inside with aniline, and on the outside with scarlet aniline dye. He always developed at some distance from the light.

Mr. KENNETT thought that ruby glass was untrustworthy.

Col. WORTLEY remarked that ruby glass was made perfectly safe if green glass were placed behind it; but then it was so dark as to be practically useless.

Captain ABNEY said that by the use of red, green, and blue glass, very remarkable combinations could be secured. By a combination of the blue and green, for instance, the purest blue possible was obtained in the light passing through.

After a vote of thanks, the meeting adjourned.

EDINBURGH PHOTOGRAPHIC SOCIETY.

On Thursday, 16th instant, Mr. W. H. DAVIES, honorary lecturer of the Society, gave the first "popular" of the season in Queen Street Hall, which was filled in every part by an audience assembled to hear a lecture entitled "Cyprus, Past and Present."

* Mr. Taylor has left England.

The LECTURER commenced by sketching the political history of the island from the earliest recorded event when it was conquered by Tothmes II. (a contemporary of Moses) to its most recent change under a British Protectorate. In dealing with the latter, notwithstanding an expressed desire to avoid controversial matters, an occasional remark slipped out, which amused a good-natured audience—indicating that Mr. Davies holds no uncertain opinions as to our Eastern policy. The lecturer next traced the history of Cyprian art, illustrating his remarks by copies of all the chief archaeological treasures discovered by General Luigi di Cesnold. These consisted almost exclusively of statuary, either carved in marble, limestone, or granite, or modelled in one or other of the plastic clays; of figures in bronze and copper; of ornaments in silver, gold, and precious stones; and of vases of earthenware and glass, from the rudest hand-made things to the most beautiful productions of the potter and jeweller. There were also toys and caricatures and grotesque figures all rescued from the earth where they had been buried for thousands of years. Of paramount interest were the beautiful reproductions of the tablets, covered with hieroglyphics, relating to the story of the Universal Deluge. While these were on the screen, a portion of the translation of this wonderful document was given: it read exactly like a paraphrase of our Biblical version. Concerning the production of these tablets, which formed part of the library of the kings of Assyria and Babylon, Mr. Davies said:—"The rulers of these regions, living thousands of years ago, were not content with the usual papyrus and reed-pen, or even with the engraved or carved records on stone, for after very careful examination of the original tablets I am firmly persuaded they were content with nothing less than the use of moveable types which were pressed into plastic clay, and then these impressed tablets were carefully trimmed, dried, and baked. This, and this only, can account for the facsimile copies of the same work with such marked variations as the different pieces of cylinders show. I do not dogmatically assert this view to be correct, as it is opposed to that of some of the most able Oriental scholars; but I do say that, looking with the trained eye of a tradesman at this old potter's work, I am not far wrong, and that numerous copies of the legend we have to-night, and of books relating to other matters, were produced in the supposed most enduring and handy materials, and then distributed to the various centres of learning or wealth. Depend upon it, these ancient people were not the preparatory monkey from which we are said to have been derived. They were, on the contrary, a highly-civilized and cultivated race of men—skilled in arms, in poetry, in building, in sculpture, in metal work, in the arts generally; and men who left an imprint upon the world, which exists at the present day." The statues were of considerable interest, indicating the various epochs of Egyptian, Assyrian, and Grecian ascendancy, and finally, what might be called a national school of art, with distinctive Cyprian expression, some were evidently characteristic portraits. "Ancient Greek civilization could trace much of its artistic and religious development to Cyprus, which ages before our British speaking people had a language, before the world we call civilized Christendom had a name, was a very thriving community, partly maritime, partly manufacturing, and largely religious, worshipping the Deity in the form of, or through the medium of, Aphrodite, Astarte, or Venus, precisely as do some of the people of the present day worship their Deity in the form of, or through the mediumship of, Mary the Mother." Among the vases very beautiful forms were found, some quite unique, others of very peculiar design, such as an annular vessel, to be seen any day in the best jeweller's windows, thus showing the persistence of some favourite ornamental forms.

The third part of the lecture consisted of views taken in the island during the past summer, illustrating ancient Christian churches, modified by Moslem requirements, some in ruins, others still used, various land and seascapes, giving a very good general idea of the island as it now is. One or two panoramas exhibited the British ironclads in the harbours, others the Indian troops encamped without the walls of a town with mosques and minarets; one showed a company of artillery on the march.

It would be quite impossible to indicate within reasonable space all the interesting features of the lecture, but it may be stated that the Society was entirely indebted to the exertions of Mr. Davies for this most interesting and instructive "popular evening." Each of the seventy transparencies was made under his personal supervision expressly for the occasion, while the attractive manner in which the lecturer was delivered rivetted the attention of about a thousand people, who frequently indicated their approbation by emphatic applause. The general arrangements for the meeting

were under the direct management of Mr. Dobbie, to whose personal exertion the Society is greatly indebted; and the lantern was exceptionally well managed by Messrs. Mitchell and Mathieson.
W. T. BASHFORD, Cor. Sec.

PHOTOGRAPHIC SOCIETY OF FRANCE.

At the meeting of the 8th November, 1878, M. PELIGOT, President of the Society, occupied the chair.

After the admission of new members, and the reading of extracts from foreign journals,

M. DAVANNE described the steps that had been taken to promote the erection of a memorial to Niepce in his native town of Chalons-sur-Saone. A council consisting of the principal men of Chalons has been appointed, who now applied to the Photographic Society for assistance in inciting a liberal response to the appeals for subscriptions, either through the individual action of its members, or by the collective action of the Society. It was arranged to nominate an influential committee to co-operate with the council at Chalons, to be composed of persons eminent in the different branches of photography both at home and abroad. On this committee, Capt. Abney and Mr. Harrison were appointed to represent England.

In the name of M. Pellet, M. DAVANNE communicated to the Society some observations on the use of ferrocyanide paper and the improvements that M. Pellet has introduced into the process. The first of these consists in floating the paper on the ferrocyanide bath, instead of immersing it, by which means the action of the developer is limited to that surface that has received the luminous impression, so that the other side of the paper remains white instead of being turned blue. To prevent the liquid from flowing over the upper side, the edges of the paper, quarter inch deep, are turned up all round. The paper thus prepared is first placed in a twenty per cent. solution of ferrocyanide of potassium, and then washed over with water acidulated with sulphuric acid; by using the latter acid in preference to hydrochloric, but in a smaller proportion, no noxious gases are evolved, and the acid is economised. M. Pellet has also succeeded in considerably improving the paper that he uses in his process; these are now of four different kinds, adapted for various purposes, and one of them is so tough and transparent as to be capable of use as tracing-paper.

A paper was then read by M. PELLET, on some experiments that he has made as to the action of the juice of beetroot on perchloride of iron under the influence of light. By pressure, a liquid of 1030° of the densimeter was obtained from the leaves of beets. A standard solution of iron perchloride containing ten per cent. of the salt at 45° B. was then prepared, and also a second solution containing ten grammes of iron salt in the same proportion, to which fifty c.c. of the juice of beet had been added; the latter solution was then made up to 100 c.c. when a slight precipitate was formed. After filtering, two portions of a piece of paper were brushed over with each of the two solutions respectively, and put to dry in the dark. A drawing executed on tracing-paper was now placed in an ordinary printing frame with its right side touching the glass, and underneath a piece of the paper sensitized with the two solutions as above described, and the whole was then exposed to the light. After some trials, it was established that to obtain a complete reduction of the salt of iron in the standard solution, it required an exposure of ten minutes to direct sunlight, while with the solution containing the juice of the leaves of beet one of from two to three minutes only was necessary. In order to determine the exact time when the complete reduction is effected, M. Pellet uses a saturated solution of yellow prussiate of potash. The paper exposed for a sufficient length of time under a tracing gives a blue colour in all the parts corresponding to the lines—that is to say, where the salts of iron have remained in the state of per-salt—while no colour is produced in the insulated parts where the iron salt has been reduced or converted into the condition of protoxide, on which the prussiate produces no action. In this way prints are obtained in blue lines on a white ground. Still further experiment showed that crystalline sugar, when added to a solution of ferric perchloride, does not diminish the time of exposure, and consequently has no effect in reducing the salts of iron. The results deduced from these experiments are:—1. That the juice of the leaves of beet have the property of facilitating the reduction of the iron salts under the influence of light. 2. That this reduction may be effected in the dry state with solutions, therefore, that have probably no vitality. 3. That the reduction is due to the oxidation of one or more organic substances contained in the leaves—such as sugar, tannin, nitrogenous compounds, and vegetable acids.

M. FERRIER recommended to the notice of the Society an instrument invented by the Commandant Faure-Biguot, for determining the size of the image on the focussing glass of the camera. In a note on this instrument, which is called the Iconometre, communicated to the Society by M. Vivien, it is described as an inverted telescope on the principle of Galileo—one, that is, in which the object-glass serves as an eye-piece, and *vice versa*. Between the objective and the object that is sighted is placed a screen pierced with a rectangular aperture, whose dimensions are proportional to those of the camera. This screen can be, according to wish, approached to or removed a greater distance from the lens, and serves to limit the field of the instrument in such a way that each distance of the screen from the lens corresponds to a different focal length. It is therefore only necessary to observe the object with the iconometre to be able to determine directly what objective to use; or, which comes to the same thing, to draw nearer to or recede from the object, to enclose a field more or less extended, in the case, that is, of using one objective only. The instrument, as constructed by M. Faure-Biguot, is contained in a small cylindrical case, of thirty m.m. in diameter by thirty-five m.m. in length; it is therefore very portable and handy for a photographer who is generally anxious to reduce his *impedimenta* to the smallest possible compass.

M. DAVANNE informed the meeting that M. Garcin, photographer of Lyons, had sent a number of plates prepared by him with gelatino-bromide, according to the instructions of M. Odagir, with a request that they might be submitted to trial. It was determined to refer these plates to the committee of the Society appointed to examine dry processes, with the request that they would report on them at a future meeting.

M. STEBBING exhibited some positive prints in salts of platinum, obtained by the new process of Mr. Willis, and demonstrated the latter by experimental illustrations. He pointed out that by the latest improvements introduced by the inventor the use of sodium hyposulphite was entirely abolished, while the prints retained intense blackness in the shadows, and pure whiteness in the lights, without sacrificing any of the half-tones. The foundation of the process M. Stebbing explained to rest on the action of light on ferric oxalate. If a piece of paper be dipped in a solution containing a platinum salt and ferric oxalate, and be then exposed under a negative, the action of light will reduce the salt of iron to ferrous oxalate. To dissolve the latter, and in order that it may react on the platinum salt, the paper is immersed in a solution of potassium oxalate, when a print is obtained perfect in all its details. In order to stop the action, it is only requisite to leave the print for ten minutes in a bath of oxalic acid, and to wash it thoroughly three or four times.

Talk in the Studio.

"HARD TIMES."—Mr. A. J. Jarman writes to us as follows:—"Noticing in your last issue of the NEWS an extract from *Mosaics*, by Mr. Frank E. Pearsall, on 'Good Prices v. Hard Times,' his remarks came vividly before me last Sunday afternoon. While taking a walk through the village of St. Lawrence, I saw coming along a photographer's barrow, drawn by a donkey; but, imagine my thoughts when I read, in yellow letters, 'H. Griggs, Photographer, Wholesale and Retail Muffin and Crumpet Manufacturer.' Talk of hard times! this man is a 'plucton'; he knows what suits this time of year. Shadows for the summer, substance for the winter."

THE "ARTOTYPE," a new printing process, apparently of the collotype class, is exciting much attention amongst our American brethren, under the name of *Artotype*. An example issued in *Anthony's Photographic Bulletin* is a very charming picture, equal to any photo-mechanical print we have seen, and superior to many. It is recommended to portraitists as sufficiently simple and excellent for ordinary portrait work.

GOLD IN NITRATE OF SILVER.—All commercial refined silver contains gold, though, perhaps, in only the most minute quantity. Of nearly three tons, which have been dissolved under the author's supervision, none could be described as perfectly pure or free from the more precious metal. English refined silver generally contains more than American stamped bars, of which a considerable quantity must be operated on in order to render the gold appreciable. If such silver be dissolved in ordinary nitric acid, containing traces of hydrochloric acids, both metals will be dissolved, and, as long as the solution is acid and concentrated, minute quantities of both chloride of silver and chloride of gold

will be retained. Crystals deposited from the liquor will also contain traces of gold. Such crystals have a faint purplish tinge, as also the solution, so that in colour it resembles water containing a very small quantity of logwood tuck. It is not known in what particular form or combination the gold exists in the silver, nor what special effect this impurity has on the photographic film. It is, however, possible that some of the troubles of photographers—as, for instance, that technically known as fogging—might, in some degree, be due to it. The impure salt may be readily prepared for experiment, by adding to a concentrated hot solution of pure silver nitrate a few drops of solution of chloride of gold. Flocks of chloride of silver holding chloride of gold are precipitated, but, by the addition of a little pure nitric acid, they are dissolved, and if the solution is set aside, crystals similar to those described may be obtained. Nitrate of silver containing gold may be purified by fusion. On dissolving the cake in water, the gold will be deposited, or may be removed by filtration through asbestos.—*Canad. Pharm. Jour.*

PORTRAIT PAINTING.—In portrait painting, as compared with historical or poetical pictures, profound insight takes the place of working invention. Claude Mellot said that he would never paint a man unless he had known him a year. The portrait painter must discern the subtle sources of expression in eye, in mouth, in features; must see what traits indicate character, temperament, will; and must be able rapidly to generalise, and permanently to idealise. The State should cause all great men, who vitally affect the life and thought of the nation, to be painted for a true national gallery, by the greatest portrait painter of the time. The greatest painter, in this sort, of our time is Millais; and he ought to be restrained to painting only the great, the noble, or the lovely. He can choose his sitters, and should now never paint a portrait that is not, in the true sense, historical. He should work for the aftertime. A great portrait painter may be exposed to the fine old conventional laudation of such critics as the late F. Bayham, who wrote in Thackeray's original *Pall Mall Gazette*, of a portrait:—" (1906) The McCullop of McCullop,—A McCullop,—is a noble work of a young artist, who, in depicting the gallant chief of a hardy Scottish clan, has also represented a romantic Highland landscape, in the midst of which, 'his foot upon his native heath,' stands a man of splendid symmetrical figure and great facial advantages. We shall keep our eye on Mr. McCullop." But such a painter as Millais is left wholly untouched by the criticism which is a product of insincere incompetency speaking in the Jargonese tongue. The great portrait painters of this day should do as great a service to the future as Van Dyck, Reynolds, and others, have done for us.—From *The Magazine of Art* for January.

To Correspondents.

- W. B. A. (Aberdeen).—Belgium sheet glass is much the cheapest and therefore the best for glazing a studio. Of course, a white or colourless glass would be a little better in regards amount of light admitted; but it costs much more, and more quickly becomes yellow, obstructing much actinic light.
- G. H.—The examples of sensitive albumenized paper you forward are so much discoloured that it is difficult to form any definite opinion in regard to them. But, so far as we can judge, the irregular stains are due to the silvering, being apparently chiefly due to scum on the surface of the silver solution. We should think also that the bath was getting weak.
- F. NUNN.—The address of Thorpe and Watson is 28, Ludgate Hill. The washings of prints may be safely mixed with old fixing baths, to be precipitated with liver of sulphur.
- B. B.—The best mode of ascertaining the proper proportion of bichromate to render gelatine quite waterproof will be by experiment. Without trying we do not know. We should try two or three grains per ounce. The best mode of obstructing the direct rays of the sun, and yet obtaining light, is to use screens or blinds of tracing cloth, which is very transparent, but will obstruct direct sunshine. A screen covered with this substance, which can be moved about as required, is useful in such a case. You need not apologize for asking questions; we always have pleasure in affording our readers all the aid we can.
- R. M. D.—A paper transparency with the image well in the body of the paper may be secured by floating the albumenized paper plain side on the silver. Float double the usual time; then print very deeply, and tone and fix as usual. When finished, use wax, paraffin, or castor oil to make the print transparent.
- D. F.—Combining the intensifying process with pyro and silver a long time will sometimes cause pinholes.

R. S. M.—Chloride of calcium placed in a drying-box readily absorbs moisture, and assists drying. Sulphuric acid has a similar property. The method of drying gelatine plates to which you refer is that of M. Boivin, described in the letter of our French Correspondent some time ago. It consists simply in placing the prepared plates in an ordinary grooved box, arranged so as to be capable of being kept level, in the bottom of which is placed a glass dish containing sulphuric acid. One of the well-known properties of this acid is its capability of absorbing moisture. At the same time, this system can only be advantageously employed when a large number of plates is prepared at once. A current of air passed through such a box is as good as anything in our estimation.

PROVINCIAL PHOTOGRAPHER.—You will find in our YEAR-BOOK just issued many advertisements of those who undertake enlargements for the profession. We cannot here recommend special bouses with propriety.

AMATEUR PORTRAITIST.—A good collodion positive is often very effective. A bromo-iodized collodion of good body; a 35-grain silver bath, slightly acid with nitric acid; a 15-grain iron developer containing fifteen minims of acetic acid; and one minim of nitric acid, will generally give good results. We prefer glass to iron plates, and we prefer a backing of maroon velvet to black varnish, as this gives a softer and more harmonious picture than the varnish. A cyanide fixing bath gives a somewhat purer tint to the whites than hypo. But a cyanide bath is better after it has been used for a time, and become charged with cyanide of silver. The question of colouring is a matter of taste. If done with great skill, it is a great improvement, but no improvement at all if badly or indifferently done. Newman's positive colouring varnish gives a fine surface for taking the colours. Let us know how you succeed.

NOVICE.—There is more satisfaction and credit, of course, in preparing your own emulsion and your plates throughout; but as a beginner, you reduce your risks very much by purchasing what you require ready prepared. Much depends upon your aim. If you wish for an exciting hobby, begin at the beginning, and prepare everything for yourself. If you wish as easily and quickly as possible to obtain pictures, buy everything ready prepared.

G. G.—The lens you mention is excellent. We cannot recommend any by name here, but, if we could, we could not recommend a better than that you propose.

HARRY POINTER.—We fear that no method exists whereby you can check the false announcements of a trade rival. If he announces himself as the recipient of medals, you can ask him when and by whom awarded; but you cannot compel him to tell you, nor can you, without risk, expose his announcements as false. The law only punishes crime, not sin; and lying, although a despicable sin, is not a crime which the law can punish.

W. H. MASON, JUNR.—The fact that the imperfectly fixed prints do not show at the time is explained by the facts which occur. When the unfixed print is placed in hypo strong enough to fix it, the first thing which occurs is the conversion of all unreduced silver into hyposulphite of silver; and this hyposulphite of silver is soluble in the strong solution of hyposulphite of soda present. But the hyposulphite of silver formed is not soluble in water or in a weak solution of hyposulphite of soda, and remains in the print in such case. It is easily decomposed by light, and when decomposed, produces the dirty yellowish or brownish stains seen on imperfectly fixed prints.

W. B. D.—Dr. Eder's address is Realschule, Troppau, Silesia, Austria.

A. B. C.—For burnishers, No. 1. We have not seen Moulton's washing machine.

JAMES CHINN.—Many thanks. We shall be glad to hear from you again.

CHARLES JONES.—Col. Wortley's paper to which you refer appears in our twentieth volume, in the number for June 23rd, 1876, and following number. Mr. C. Bennett's process appears in our last volume, and in our YEAR-BOOK just published. Colonel Wortley's uranium process appears in our volume for 1872.

A. E.—The print is manifestly fading, and suggests the same conclusion to our mind which we first expressed in relation to the coloured one, namely, that something in the mounting analogous to corrosive sublimate in paste was in operation. It is not probable that such can be the case in a print mounted by a photographer, but the appearance suggests something of the kind. We can find no really satisfactory solution. The many mysteries of the fading of silver prints are fast finding out! When permanent printing processes exist, it is amazing that another silver print is produced!

W. COLQUHOUN.—Thanks.

ERNEST DUNY.—Thanks. The Diploma has not arrived. Was it sent by post?

ERRATA.—In Mr. W. B. Doyle's letter on "Substrata for Dry Plates," in our last, page 33, second column, fourth line, first word, for "pure," read "puce"; same page and column, fifteenth line, last word, for "substitute," read "substratum."

The Photographic News, January 31, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY IN COLD WEATHER.—M. ERNEST LACAN AND MR. THOMAS SOPWITH—THOMSON'S CYPRUS.

Photography in Cold Weather.—A can of hot water in the dark-room is a desirable thing this weather in the event of the apartment not being otherwise warmed. Complaints about the insensitiveness of the dipping bath and the sluggish action of the developer are not unfrequent if the solutions become chilled, and work, as every photographer knows, is considerably impeded by cold weather. A luke-warm developer will very frequently bring out a result which a solution that every moment bids fair to freeze is quite incapable of yielding; while photographers must always remember that the solubility of a liquid is sometimes materially impaired by its being very cold. A hot saturated solution of bichromate of potash, for instance, contains much more of the salt than a solution at 32° Fah., for as the liquid cools it will be found that salt becomes precipitated. But it is not only that cold impairs the degree of solubility in liquids; it exerts also physical effects in the photographer's dark-room. A glass plate, for example, cleaned in a cold room and then brought into a warm one, gets covered with moisture, and in this condition is very susceptible of injury. If the collodion is simply poured upon the plate, no great injury is done, for the collodion will flow all the more smoothly, most likely; but if, as most photographers are in the habit of doing, a camel's-hair brush is drawn across the surface, and moisture happens to be deposited thereon, a streaky plate is the inevitable result. At the same time, the dark-room, we hold, should not be too much warmed this weather, since the difference in temperature at night and day is not without an injurious influence upon the photographer's requisites. A small stove in the dark-room—unless the latter happen to be large, and be employed, say, for the sensitising of paper as well as for other work—is hardly to be recommended, for if collodion, ether, or alcohol are in immediate proximity, the risk is naturally very great. A photographer has more to fear, in fact, from extreme heat than extreme cold. Where the dark-room used specially for operating is but a closet, the best thing is to have a can of hot water standing therein, which may be changed every hour or two, and which diffuses warmth enough. If developer is to be warmed, this may be best done by holding the beaker containing the solution in the warm water for a moment or two, when the chill will be removed sufficiently for working under normal conditions. We must, however, warn operators to especially beware of cyanide and bichromate in cold weather. The circumstance of having to do with warm and cold solutions is apt to lead to chapped hands and chilblains; some people, indeed, suffering from these annoyances under very little provocation. In these circumstances one cannot be too careful in handling solutions. In the case of chapped hands there is sure to be some fissure in the cuticle, while with chilblains the skin is so tender and swollen that its breaking is always imminent. Cyanide of potassium and bichromate of potash are bad enough to have to do with in the case of a whole skin, but when the latter is broken the result may be exceedingly dangerous. There is on record the death of a photographer who simply dipped a sore finger into cyanide; and bichromate of potash, which is employed by some every day in the sensitizing of tissue, would prove hardly less dangerous under the circumstances. Both salts in solution penetrate the system through the skin—cyanide, in fact, having a soluble effect upon the cuticle; but if they act upon a naked wound, the effect is quick and striking. Rubber finger-stalls offer such a perfect and simple safeguard, that they should always be at hand in a photographic laboratory to secure one from the effects of bichromate; while as regards cyanide, there is, under ordinary circumstances, no reason whatever for its use. Cyanide of

potassium should be banished from the studio and dark-room for general work, and only for experiments in photochemistry, or in isolated cases—as, for instance, in the cleaning of Daguerreotypes—is really necessary.

M. Ernest Lacan and Mr. Thomas Sopwith.—Two deaths in the photographic world are to be noted. M. Ernest Lacan, who has been for so many years connected with this journal as Paris Correspondent, has just died—a man whose acquaintance with photography and photographic literature is from a very early period. M. Lacan was short of stature, brisk and energetic in manner, and with an address that was peculiarly taking. To a foreigner who was not well versed in the French tongue M. Lacan's address was particularly pleasing; he would suggest the word that your tongue hesitated to pronounce, or, to give confidence, utter a sentence in English now and then, thus rendering the conversation at once more intelligible and pleasing. M. Lacan executed some important work in connection with the municipal literature of Paris, employing his photographic knowledge to some purpose in the reproduction of old sketches and MS. During the siege of Paris, M. Lacan remained in the city, but was perforce compelled to leave his home for the time being. His residence, situated in what was once termed the *Avenue de la Grande Armée*, but now rejoicing in a more republican title, was beyond the *Arc de Triomphe* and the *Champs Elysees*, in the direction of Versailles, and not far from the *Porte Maillot*, and consequently under fire from the Prussians nearly the whole time of their investment. The district around was rendered unsafe by the falling shells, and hence M. Lacan's withdrawal. When he went back to his residence, although this had not suffered, there was evidence in every direction of damage done to houses and property. Here, a big shell had crushed a house like a bandbox, and sent its walls into fragments; at another spot the missile had struck the cornice and taken an angle off the masonry. In some cases, where the shell did not burst, it was found in the cellar, having made a daylight perforation from roof to basement. But M. Lacan's sufferings were not so much due to shells as to scarcity of provisions during his enforced residence in the centre of the capital, and, if we remember rightly, it was one of his friends in London, no other than Dr. Phipson, who was the first to send our late collaborator a case of provisions on the breaking up of the siege. Those who personally knew M. Lacan will remember him as a bright, kindly little gentleman, ready and anxious to assist all, who might visit him, in getting a peep at photographic life in the French capital. The other gentleman whose loss we deplore is Mr. Thomas Sopwith, M.A., F.R.S., for a long time a member of the Photographic Society, and many years one of the referees of the Amateur Photographic Association, his colleague being Mr. Glaisher. Mr. Sopwith was best known as a mining engineer, and published many valuable records and data upon mineralogical subjects. Two or three volumes of travelling reminiscences also emanated from his pen. He took a keen interest in photography, both in respect to its scientific and pictorial association. When gun-cotton was first tried for mining work under his superintendence, Mr. Sopwith conceived the idea of having the various results produced in blasting photographed, so that the record might be as impartial as possible. The rent and fissure made in a rock by equal weights of one explosive or the other was thus truthfully rendered. Mr. Sopwith took considerable interest in the advancement of photography, and was no stranger at the meetings of the Photographic Society, while his face has also been seen at the Solar Club, and at other social gatherings connected with photography. Mr. Sopwith was born in 1803.

Thomson's Cyprus.—We made mention last week of Mr. Thomson's book on Cyprus, or "Through Cyprus with the Camera," as it is called. We are glad to see that the delay we spoke of is at an end, and Messrs. Sampson Low and Co announce that the two volumes are now ready for publication. The book is likely to prove the best reflex we have so far had

of Cyprus and its inhabitants, for the photographs which illustrate the pages were taken so recently as last Autumn. Her Majesty has taken some interest in the work, and the first order received for a copy of it emanated from the Royal library.

ART IN PHOTOGRAPHY.

BY J. CROTHWAITE.*

WHATEVER description or line of art is followed by the student or practitioner, it is of importance that a knowledge of the fundamental or elementary principle should be obtained, otherwise his work must be produced at haphazard, and the title of "artist" cannot rightly belong to him.

If a picture be faulty in selection of point of sight, in perspective, or have incongruous objects introduced, however good the workmanship or mechanical part, it will be more or less objectionable to those of cultivated taste or trained eye who may happen to see it. The dissemination of some knowledge of the principles of general art amongst photographers is extremely desirable. We do not certainly see now the gross mistakes from an art point of view that were formerly perpetrated. They have been so loudly condemned and noted by the public and the press that a general improvement has been the result; but there is room for still further improvement, and any advance in that direction can arise only from an increased and enlarged acquaintance with the principles governing true art, and by the careful study of good examples.

Of course an extreme knowledge of forms, effect, and style is, perhaps, not so absolutely necessary for the photographer as for the artist pure and simple; but the larger and more general the knowledge of art possessed by the photographer, the more surely, if he have any art feeling, will his productions be more or less imbued with the true spirit of art.

I know well the difficulties in the way of some photographers, which prevent, to a great extent, the development and utilization of their artistic knowledge—a limited studio, possibly a limited command of money wherewith to obtain the necessary accessories and apparatus for the production of art studies; in addition to which is the daily routine of the studio—the obligatory production of a certain class of work which has to be done, come what will—the class of sitters, so well known, who will have the stereotyped poses and lighting, who object to black faces and heads any way out of perpendicular—all these things tend to make it difficult for some men to realize their ideas of the combination of art and photography. There is no doubt that to produce high-class work, and work that shall not be open to the charge of monotony, an extensive stock of apparatus and accessories is absolutely necessary. Work of a high class, and which may lay claim to artistic merit, may be produced with few and simple appliances; but when these appliances have been used for the production of hundreds or, perhaps, thousands of pictures, the thing, to say the least, becomes rather monotonous.

To the artist with pencil and brush this is a matter of little importance. He may stock his sketch book with studies of accessories and backgrounds to be used and combined in any manner he may consider advisable; but the photographer is limited to the presentation of real objects, which must be actually combined to produce the requisite effect. If a portion of the money annually expended in posing chairs, artificial furniture, and mysterious combinations and structures (which might be worshipped without breaking the second commandment, as they are certainly not the likeness of any thing in the heavens above, the earth beneath, or the waters under the earth), was spent in the purchase of good artistic furniture, such as we see in daily use, we should not be

distressed by the sight of so many artificial-looking pictures, where we see the same chair, table, footstool, &c., repeated *ad nauseam*.

It may be thought—and I have heard it said by some—"What better shall I be by devoting myself to the study of art? My business is a prosperous one; I have as much work as I can do. My object in business is not to carry out any Utopian ideas as to the elevation of the art. Let the public elevate themselves. I make money; what more do I want?" We hear it often remarked, too, that men with high artistic feeling are not generally successful men; and cases are cited of photographic artists who have not been money-making men—perhaps the reverse. To holders of these opinions, I have not a word to say; a man whose ideas are purely utilitarian is without the pale of those whom I would address. Every man, it is said, has his hobby; and if we make art our hobby we need not ride it to death. Commercial success and artistic photography are perfectly compatible, as innumerable instances testify.

A little time devoted to the study of art will largely repay the student as a mental pleasure, if not always in a pecuniary manner; and, as it forms such an extensive department of photographic work, its study to a greater or less extent becomes a necessity, if we would reap any measure of success. It is becoming daily more and more recognised. The shop-windows are full of cleverly-posed and lighted portraits of the temporary beauties of "society." Our patrons are gradually, and, perhaps, to themselves unconsciously, becoming educated to the higher walks of photographic art; and the stock poses and furniture will not much longer satisfy the demand upon our art. The standard of our general work must be higher, or we shall certainly be left behind in the race for success; and the only way to obtain a place in the ranks of artistic workers is by making art a study, noting assiduously the various changes and effects in nature, and by carefully examining good works of art.

No recipe can be given for picture-making. Success depends mainly upon the feeling and education of the producer. An ardent love for his profession and a strong desire for excellence will inevitably lead to the development of real artistic feeling. "The mind," says Sir Joshua Reynolds, in his Sixth Discourse, "is but a barren soil which is soon exhausted, and will produce no crop, or only one, unless it be continually fertilised and enriched with foreign matter. The greatest natural genius cannot subsist on its own stock. He who resolves never to ransack any mind but his own will soon be reduced from mere barrenness to the poorest of all imitators; he will be obliged to imitate himself, and to repeat what he has often before repeated."

A knowledge of the principle governing composition and light and shade may not be applicable directly to the production of a photograph; a man may possess all the available resources of the photographer—mechanical, optical, and chemical—yet, if his art education have been neglected, his pictures, though they may be excellent specimens of manipulation, will yet want that nameless something which distinguishes an intellectual production from a photographic representation.

It is true that between painting and photography there is a material difference. The same laws apply to both, but the mode of procedure is different. The painter can arrange and compose pretty much as he pleases. The photographer is limited to the arrangement provided by nature—that is, in the department of landscape art; but even in that case much may be done by a judicious selection of position, so as to avoid some portion that may be unsatisfactory, or to introduce some feature that would enhance the charm of the subject. A careful and accurate consideration of the different effects visible at different periods of the day is of great importance, and cannot fail to be of the utmost use to the landscape artist. The mind

* Read before the West Riding of Yorkshire Photographic Society.

cannot be too attentively fixed on Nature's workings; for her effects are inexhaustible and ever changing, awaiting only the notice of the trained eye and hand to obtain a lasting and permanent record of their transient beauty.

Upon the size and relative position of the masses of light and shade in a picture depends the general effect of the composition—contrast producing upon the mind of the spectator a sensation of energy, while a subdued effect, consisting principally of gradations of half-tints, produce a feeling of rest and repose. The extent to which these effects are introduced must always remain a matter of taste, and the proper introduction of them a matter of education—the one great necessity being a careful and systematic treatment of the materials employed.

The rules must not be considered as at all contrary, but simply as forming a basis upon which any special effect may be constructed, and which are capable of very considerable modification, but a knowledge of which cannot be neglected in any branch of pictorial art, the more especially as combination pictures are now so common and so frequently produced. In these pictures the art principles are of the utmost importance, otherwise the composition may be wanting in keeping or in perspective, the selection and arrangement of the various negatives employed requiring a great degree of skill and judgment on the part of the composer. The proper fitness must be maintained, and a judicious attention paid to the probabilities of the story intended to be told. Appropriate dress and accessories contribute largely to the success of the work. A great variety of expression may be given by only varying the position of the head and neck. The hands, also, are great aids in expressing emotion, as numerous examples existing in the public galleries, which have been made familiar by engravings, will testify. Perhaps the celebrated Last Supper, by Da Vinci, will demonstrate the powerful expression of the hands as well as any picture I just now remember; indeed, in every way the picture will well repay a considerable amount of careful study being given to it.

In my next paper I propose to produce several illustrations to this end, one evening proving too short to enter into the matter with any great degree of advantage—the more so as these preliminary remarks have already greatly exceeded my intention.

ON THE FADING OF THE UNDEVELOPED PHOTOGRAPHIC IMAGE AND ON SOLUBLE BROMIDE IN EMULSIONS.

BY CAPTAIN W. DE W. ABNEY, R.E., F.R.S.*

BEFORE proceeding farther, I should like to show what action the potassium nitrite really effects. We have bromine liberated, remember. The equation then runs as follows:—

It is evident that to obtain this result we must have the presence of a minute quantity of water. Now, the potassium nitrite rapidly absorbs moisture, so there is no difficulty on that score.

A study of this equation led me to another experiment. It appeared that though potassium bromide (or, presumably, any alkaline bromide) might not affect sensitiveness, it was by no means certain that hydrogen bromide—that is, hydrobromic acid—might not be a destructive. Supposing that to be the case, was it not possible to avoid its formation, and to cause it to be replaced by an alkaline bromide? If we substitute potassium hydrate (KHO) in the equation we should effect this. This was tried, but alas! the result was not satisfactory. The fact is, that potash and pyroxyline rapidly reduce silver bromide to the metallic state. It then occurred to me that a carbonate of an alkali would

answer as well. The result justified the expectation, the plate was perfect. The equation then runs as follows:—

I believe that I was correct in claiming these two discoveries as my own. I am perfectly well aware that it has long been known that sensitiveness is caused by applying a bromine absorbent to the film; but the fact that a large quantity of soluble bromide may be left in the film, and that no serious diminution of sensitiveness occurs, is, I believe, new. The combination of the alkaline carbonate is also, I believe, new. I have already pointed out, in a paper to the Royal Society, that sodium sulphite and potassium nitrite may be usefully applied to a film to prevent the oxidation of the film. It will be seen that they play a second useful part, in that they also absorb bromine. The addition of either of these bodies with a carbonate tends much to increase their value, since in both cases we have the formation of any acid prevented. The addition of organic matter, as used in a preservative, has the same effect as the potassium nitrite or sodium sulphite, or such other bodies; but its absorption of bromine is much slower—in other words, it has not such an avidity for it as the latter inorganic compounds, hence the sensitiveness is diminished when trusting to it alone.

There is another moral to which these experiments point. Supposing in making an emulsion with bromide in excess we use zinc bromide alone, it will be found that the effect of the nitrite is much diminished, and a more thorough washing is requisite than if an alkaline bromide be substituted. If, however, we use zinc bromide (say) and ammonium bromide together, and have a defect of silver nitrate, we shall find that the whole of the zinc bromide is converted before the ammonium bromide is touched; hence in this case any excess of bromide will be that of an alkali. With an emulsion thus formed, the nitrite would still be effective, and all the advantages of the use of zinc would also be obtained.

Now, the Society may ask, what earthly connection can this part have with the first part of the paper? It is this. By applying an alkaline carbonate to the film all nitrous acid liberated from the pyroxyline is immediately absorbed to form an alkaline nitrite, and the destruction of the photographic image from this cause, at all events, can be avoided. It is somewhat curious how one application of chemical knowledge aids us in determining another. The members of the Society are all doubtless aware of the necessity that exists of fuming with ammonia sensitized albumenized paper, from which has been washed out all free silver nitrate. They will also be aware that with collodio-chloride on glass or paper ammonia materially aids the vigour of the print. Up till lately I have always been under the delusion that in one case the ammonia combined with the silver chloride; and in the other with the silver nitrate, to form ammonia nitrate of silver. These reactions, however, are not necessary. When ammonia comes in contact with chlorine we have a compound of chlorine and ammonia formed which may decompose almost instantly, and form nitrogen and hydrochloric acid. Now hydrochloric acid, if formed, would give us a measly print; but this is prevented by the combination of the hydrochloric acid with the excess of ammonia present.

A further discussion of this, with some other points, I mean to bring forward on a future occasion. I had hoped to have said something regarding the spots to be found on washed emulsion; but I must confess that new phenomena in the investigation have presented themselves to me, and I do not wish to say anything regarding them till these have been thoroughly sifted.

I am afraid that my statements have been somewhat prolix, and perhaps disconnected. It is hard to me at all times to put a subject in the shape in which it shows to the bes

* Continued from p. 39.

advantage, and I feel that my paper to-night will not appear in that guise. I cannot help thinking, however, that the facts I have brought before you are really important ones, particularly in the preparation and application of emulsions.

A film containing bromide in excess is always cleaner and freer from spots than one in which even a small quantity of silver nitrate is present. How to utilize the former to the best advantage I think I have shown you.

The following is from the *Journal* of the Society:—

COL. STUART WORTLEY observed that some years ago he had found very satisfactory results with reference to the keeping qualities of pyroxyline follow from washing the pyroxyline with a solution of ammonia. He had kept pyroxyline so prepared for four or five years without any sensible deterioration, whether the pyroxyline had been made from cotton or from paper.

CAPT. ABNEY inquired whether the pyroxyline had been kept in bottles?

COL. WORTLEY: Yes; and in brown paper envelopes. Previous to washing the pyroxyline with ammonia, the acid it contained used to eat away the paper of the envelope, but now this never happened.

MR. SPILLER considered the use of the alkaline nitrite was a very interesting discovery. He gathered from the paper that Capt. Abney preferred now to use an alkaline carbonate in conjunction with a nitrite, the change being that the nitrite was converted into a nitrate, the presence of the carbonate providing for the elimination of carbonic acid. With reference to the formula quoted by Capt. Abney, he (Mr. Spiller) would suggest that, instead of using potassic nitrite in conjunction with sodic carbonate, it would answer the purpose better to employ potassic carbonate. The action of the two bodies of the latter class, he thought, adhered better to the system laid down by Capt. Abney some time ago, namely, that it was more advantageous to use substances of a deliquescent character in the preparation of dry plates.

CAPT. ABNEY observed that he only brought the present formula forward as a specimen. He had tried all possible combinations, and he gave the result of the one he had mentioned to-night simply as a result that he had obtained. He fully agreed with Mr. Spiller that it would be better to use potassic carbonate in preference to the sodium salt. With reference to Col. Wortley's washing of pyroxyline with ammonia, he might remark that, as having experience with pyroxyline of the explosive kind, the ammonia was useless if decomposition had once set in. If the pyroxyline had dried before washing with ammonia, the latter could not prevent spontaneous decomposition. The only chance with ammonia was not to let the cotton dry before using it. With regard to explosive cotton, the great difficulty was to preserve that "tottering equilibrium" which an acid condition rapidly upsets.

COLONEL WORTLEY said that he washed the pyroxyline immediately after it came from the acids.

MR. SPILLER said that he remembered, some thirteen or fourteen years ago, when he was working with Professor Abel, in the War Department, that a French chemist brought before the French Academy the action of ammonia upon pyroxyline, asserting that definite combination was set up between the two. Professor Abel and himself therefore set to work and found that ammonia really did combine with pyroxyline, and it was an open question whether or not ammonia, in that case, did not have some effect upon the quality of the collodion made from pyroxyline so treated.

COLONEL WORTLEY remarked that negatives made with pyroxyline washed with ammonia were much denser than those with pyroxyline not so treated. Acid in collodion gave a thinness of image, and he attributed the density in the former case to the perfect elimination of the acid by ammonia. Of course he used the latter very weak.

MR. SEBASTIAN DAVIS had noticed that decomposition in collodion used to take place much more rapidly years ago than it did now. He had some specimens which had been made three or four years ago, which were apparently unchanged. He considered it essential, however, that the pyroxyline should not only be thoroughly dried, but should also be kept in a dry condition. His method was to dry it in a water-bath raised to the temperature of boiling water; and although at one time there was considerable doubt as to whether or not gun-cotton

would explode at that heat, he believed that if conducted with proper precautions there was no danger of an explosion. He thought that the disengagement of iodine when potassic iodide was added to the collodion was not necessarily a sign that the collodion was decomposed. Years ago potassic iodide was used as being the most sensitive salt, although its sensibility gradually lessened after keeping about forty-eight hours.

CAPT. ABNEY observed that his experience with drying pyroxyline by means of a water-bath did not coincide with that of Mr. Davis. He thought that a temperature of 212° was decidedly dangerous, and he had had two or three ovous destroyed through drying pyroxyline at that heat, although he was not prepared to say whether it was the fault of the pyroxyline or through neglect of the attendants. He had also found that in drying emulsions by means of the water-bath decomposition was very apt to set in. With reference to Mr. Davis' remark as to the liberation of iodine, he did not mean that potassic iodide added to pure solvents would not liberate iodine. No doubt, with pure alcohol and pure potassic iodide, no discolouration would result. But other, also, had a direct effect upon potassic iodide, and the latter underwent decomposition in its presence. If, immediately after iodizing, the collodion remained discoloured, it might show the effect of nitrous acid. He was strongly against drying pyroxyline in a water oven.

MR. ENGLAND wished to know if the formula recommended prevented the image from fading.

CAPT. ABNEY replied that potassic nitrite in conjunction with an alkaline carbonate ought to give this result, but not when used alone.

MR. ENGLAND was inclined to think that the cause of fading was due to the kind of pyroxyline used. At the Paris Exhibition he had exposed a large number of negatives, and those which were developed immediately were perfectly successful, but those which were kept some time—most of them duplicate negatives—were, in the majority of instances, total failures. He had used two kinds of collodions, which he might call Mr. A's and Mr. B's. The first developed very well, but the second gave only a faint image which no amount of labour would bring up. The preparation in each case—emulsion plates—was exactly the same.

CAPTAIN ABNEY remarked that it was these failures of Mr. England which had set him thinking over the matter. He had worked from point to point until he had arrived at the adoption of an alkaline carbonate to solve the difficulty.

In reply to Mr. England, Captain ABNEY said that unless the sulphite was used in combination with the carbonate when the pyroxyline was at fault, the sulphite became exhausted, and so the image was attacked.

MR. VALETINE BLANCHARD observed that iodine was liberated from collodion from other causes than from decomposition of the pyroxyline. If, in iodizing, the collodion became rapidly red, then we might look for the cause in the ether.

CAPTAIN ABNEY: That would probably be acetic ether.

MR. BLANCHARD: The test for the ether is potassic iodide. If on using it turns red immediately, then the ether is not suitable. With regard to the method of storing the pyroxyline, he thought that the plan proposed by Col. Wortley, of keeping the pyroxyline in paper bags, was an excellent one, because it supplied a test for the decomposition of the pyroxyline. Ammonia should be applied before the pyroxyline was dried; afterwards it could not stay decomposition.

CAPTAIN ABNEY thought that the change of colour could not be due to the ether, but to some interior decomposition set up.

MR. BLANCHARD said he had had samples of other which on mixing with the iodide instantly turned red. He had had some conversation with Mr. Williams on the subject, and was told by that gentleman that the ether in question was known as "ozonized."

MR. PAYNE JENNINGS stated, with regard to the fading of the image, that he had found the use of carbonate of ammonia recommended by Mr. Warnerke to be most satisfactory.

MR. ENGLAND remarked that this did not agree with his experience. The plan of Mr. Warnerke had totally failed in his hands. He had tried soaking the plates even to twenty minutes or half an hour, but did not succeed in bringing up the image. Perhaps the plates of Mr. Jennings had not been kept long between exposure and development.

MR. JENNINGS: About a fortnight.

MR. ENGLAND: Mine had been kept several weeks.

THE CHAIRMAN remarked that the paper presented a happy combination of the theoretical and practical. He was pleased

at this, because theory was only properly tested when put into practice. When experiments bore out what had been previously advanced by theory, good results were sure to follow. Captain Abney by his paper that evening had broken new ground, and he was sure the meeting would accord him a hearty vote of thanks.

PRELIMINARY EXPOSURES OF PAPER.

PURSUING the subject of preliminary exposures of sensitive paper to light, to secure quick printing and harmonious pictures, Mr. De Silva continues his remarks in *Anthony's Photographic Bulletin*. He says:—

"When I gave my sensitive paper a preliminary exposure to light, I had a special object in view: there was an objectionable contrast in the picture, and I wished to modify it, it being impossible to obtain another negative for at least six months to come. I exposed the paper under a piece of plain glass (in the sunlight) until a faint tint was visible—as near as I could estimate from one to two seconds of time would suffice—making allowance, so that after the picture passed through the subsequent operations of toning and fixing, a very faint tint would be visible. I have written 'from one to two seconds,' using white paper, one second would be enough: but on a tinted paper it would require a little more, otherwise it would not be visible—the law of contrast having a bearing on this point; markings which would be readily seen on a white ground, would require to be much darker to be discerned on a tinted one. I have again and again repeated the experiments, and always with the same results. I do not know that the actual time occupied in printing the picture is less on the pre-exposed paper than on the ordinary; but of this I am positive, that in order to get the same amount of detail in the lights (on ordinary paper), with the test negatives used, the shadows and middle tints would suffer considerably. In the case of the portrait, the portions underneath the mask were about one-fourth the depth required in a fully printed proof. Should the paper have been fumed with ammonia, it must at once, after it has been exposed to light, be placed upon the negative (unless it has been some time since the fuming was done), otherwise there will be a perceptible difference in the colour of the tint and the picture. *En passant*, on looking over landscapes in which clouds have been printed in, a deal of difference will often be noticed in the colours of the sky and the landscapes; not only is this occasioned by the difference in colour of the two negatives, but the change in the conditions of the paper which has taken place between the printings, one portion toning more rapidly than the other.

"I have before described in the *Bulletin* the method I adopt in preparing my paper; but thinking that it also might have some bearing on the case, I will jot down a few items; and if all who take interest in the matter will follow them precisely, and again try the experiments, I have no doubt they will arrive at the same conclusions that I have. My silver bath is clean,* and kept neutral with ammonia. I silver my paper in a warm room, and am most careful not to expose it to white light until I cut it up to go into the printing frames; thus I am enabled to keep my paper good for a very long time—in the winter for weeks. When it is perfectly dry—bone-dry—I submit it to the fumes of ammonia for about twenty-five minutes; if I intend to keep it several days I fume it longer. During the fuming it becomes somewhat limp. I then roll it sheet by sheet into a solid roll, and keep it shut up in a box until required for use. It must be borne in mind that a neutral bath requires to be somewhat richer in silver, otherwise the albumen will be dissolved off; that when the

paper is intended for long keeping, it should be floated longer, or it will print measly—secure a mean between 'measles' and 'woolliness,' the latter being occasioned by floating too long and also by exposing the paper to ammoniated fumes before it is thoroughly dry, though with paper long kept there is not much to fear from over-silvering, providing the sheet is drawn over a rod as it leaves the sensitizing solution. The prints tone readily, and brilliantly. Previous to toning, it is necessary to add a little acetic acid (say an ounce of ordinary to the gallon) to the first washing water, allowing them to remain in it until they are of a deep cherry red colour, not longer, and moving the prints about to insure an even action of the acid. The fixing will take a little longer; on holding the prints to the light, to determine whether they are fixed or not, care and judgment will be required to distinguish the structure of the paper from the unfixed parts, and it is better to be on the safe side and allow them to remain in the hypo a little longer, which I will presume any truly economical photographer makes fresh every day.

"The prints enclosed were made on paper which had been silvered early in December last, thirty-five days previous to printing. They have received very rough usage, having been in a specimen book since March, for which allowance must be made. They were rolled on a hot-plate press; had they been burnished, they would have presented the appearance of sand-paper, for burnished prints stand no wear and tear.

"I should mention that the paper used had a very slight rose tint; by using neutral silver bath, and fixing bath new and not weaker than one to eight, the colouring matter is so toned down as to be very agreeable. I have found that white paper of the same brand does not keep so well, not only in point of whiteness and brilliancy, but it is apt to work measly after ten days or a fortnight. I have an idea that the colouring matter adds to the keeping qualities of the paper, but I scarcely care to positively assert it, lest I should be entirely gobbled up by the critics; however, I think it would be worth inquiring into. During the winter months the pink paper so prepared as above works admirably for every class of work—for vignettes even for two or three days. While it possesses one great advantage, the surface being thoroughly dry and hard, it does not get frozen in the frames, and the annoying speckled appearance of the prints occasioned by the frost on freshly-prepared paper is avoided.

"Small details (often overlooked) make up a great whole. On reading over the report of the meeting of the N. P. A. at Buffalo, I was forcibly struck by the precise way in which one gentleman described the way in which he prepared his paper. He said:—'I silver my paper one minute to one minute and a-half on a 40-grain bath; I then lift it gently from the dish (in order not to take up much silver) and hang it up to dry.' Now, had that gentleman used a glass rod, over which to draw his paper as it left the bath, most assuredly he would have told us so; but (for that brand of paper) he would have prolonged the floating, for the rod would have scraped off nearly all the free nitrate, and his paper would have printed measly (under-silvered); whereas he left some on it—sufficient to convert the salting and albumen into chloride and albuminate of silver, leaving enough free nitrate to complete the operations successfully.

"And so I leave the subject of preliminary exposure, believing it a valuable aid in case of necessity, as many will no doubt find out; never for a moment advocating the injudicious use of it. It must be done, to be done well, with care and judgment."

[It appears to us that the method proposed is well worthy of careful attention, as the preliminary exposure will serve to give the initial force to chemical action, which, if judiciously managed, need not in any degree lower the whites, and, if continued until a tint is produced, give more harmony to prints from hard negatives.—ED. PHOTOGRAPHIC NEWS.]

* Too much importance cannot be attached to this. The bath should be kept in the light, and boiled occasionally. When the bath is full of albumen, the paper will have a peculiar lustre—if I might so express it, a metallic lustre—resembling very faintly the appearance of silvered albumen paper submitted to sulphurous fumes; in this case it will be necessary to print much deeper and tone more, as the prints are reduced by the hypo fixing bath considerably.

IN MEMORIAM.

WE have to announce, with deep regret, the death of an esteemed friend, and one of our oldest *collaborateurs*, M. Ernest Lacan, our Paris Correspondent, who died somewhat suddenly on the eighteenth instant, at his residence in Paris. M. Lacan was the *doyen* of photographic litterateurs. His name will be familiar to the oldest photographers as one of the first associated with photographic literature. He was Editor of the *Moniteur de la Photographie*, a journal which he established many years ago, after having, during many previous years, contributed to other photographic journals, as well as to scientific literature generally. Our readers will remember, during the long period in which he has been on the staff of this journal, the lucid and comprehensive epitomes of photographic and scientific progress in France he laid before them; and many will remember personally the ready and amiable courtesy with which he was ready to aid them in Paris. Although a veteran in photographic literature, M. Lacan had only reached middle age. Personally, he was exceedingly courteous, amiable, and accomplished, and possessed a singularly winsome bearing. He was for many years sub-librarian to the City of Paris, he was a member of the Society of Men of Letters, Officer of the Academy and of the *Nichan Itikaar*, and Chevalier of the Royal Order of Ernest Auguste of Hanover.

SIZE OR PROPORTION IN PORTRAITURE.

IT must strike any one who reflects on the subject, that it is marvellous how little attention has been given by photographic portraitists to the subject of scale or proportion in portraiture. The boast of photography is its literal accuracy and uncompromising faithfulness to truth. Yet there is no element of likeness more important than relative size, an element which has hitherto apparently received no attention whatever. A general proportion has been adopted by portraitists; but each man has been a law unto himself. The aim has been to fill the plate with fair proportions without crowding it. If the figure were too large for the plate, it looked clumsy; if too small, it looked weakly diminutive, and required too free a use of accessories to fill out the space. The portraitist's idea of pictorial fitness has governed the matter, with, in many instances, no thought whatever of representing the sitter in truthful proportions, or any approach to an actual scale.

Who that has looked through a photographic album has not at times been struck by a curious incongruity in the act that the portraits of some gentleman and lady whom

they knew, husband and wife, presented such a false idea of their relative size? The lady, possibly a *petite* person of slender build and small proportions, towered large on the card a perfect Amazon; whilst her husband, really a stalwart man, photographed on a diminutive scale, presented a small feeble person, half the size of his wife. The solid fine head of a Huxley has looked diminutive beside the microcephalous cranium of an idiot taken on a large scale. Or, again, a son of Anak has been dwarfed by being taken low on the plate, whilst a diminutive lady has been made almost a giantess by being taken high upon the plate, whilst her flowing train concealed her feet.

In our YEAR-BOOK for 'seventy-nine Mr. Spiller points out for the first time this incongruity in an article entitled "A Plea for Standard Sizes in Portraiture," which we reprint in the present issue. That the literal truth of which photography is supposed to be the embodiment demands attention to such a standard, cannot be doubted. Some time ago *Punch* made merry over the photographic portraitist who was supposed to have made himself popular by keeping on hand a miniature suite of furniture and accessories, in order to give importance and apparently increased stature to sitters of insignificant appearance. The notion was amusing, but every one felt that any such sham actually carried out would be contemptible. Yet something quite as destructive of literal truth has been adopted in constant practice, not, indeed, with the attempt to deceive, but from sheer thoughtlessness. Mr. Spiller justly complains that a head of Faraday, the noblest of modern philosophers, is made to appear diminutive beside some far from being his peers, simply because of the relative scale on which they are produced. He pleads, therefore, for the adoption of a definite scale which shall better satisfy the sense of right, and may also admit of some approach to measurement or absolute estimate of the proportions of the original of each photograph.

Mr. Spiller suggests the advantage of adopting a scale of about one-tenth the size of life as a general standard. Such a proportion would doubtless possess many advantages. But it is manifest that the scale must be dependant upon several considerations. First, the size of the picture, whether carte, cabinet, or larger; next on the style, whether full-length, three-quarter, or bust only. And, indeed, it is clear, looking at the matter in this aspect, there must be several standards, one for each size and each style of portrait. The usual proportion for a standing figure in a card portrait is a length of from about two inches and a-half to two inches and three-fourths. This, it will be seen, gives a proportion of about one-twenty-fifth the natural size of a man of middle height. On a cabinet size the standing figure should not exceed four inches and a quarter or four inches and a-half in length, which would give a proportion of about one-fifteenth of the human figure. For bust portraits, either in cabinets or cards, the proportions must, of course, be different. On a card, the head in a bust portrait should not much exceed one inch in length. And assuming nine inches as the average length of a man's head, a proportion of one-ninth is easily attained. In cabinets the length of the head may be from an inch and a-half to two inches, and a proportion of from one-sixth to one-fifth decided upon.

The absolute decision of proportions should not be decided *ex cathedra* by any one, but should be the subject of consideration and discussion, and be decided by general agreement. A paper read before the Photographic Society, if Mr. Spiller, to whom by right the task would fall, if he accept the duty, would break ground for discussion, although we fear little would be effected by verbal discussion. The more thoughtful consideration and discussion to be obtained through the pages of the journals would probably be much more effective and more eventually satisfactory, because of its deliberation and thoughtfulness. We shall have pleasure in offering our pages in aiding such a discussion, and invite those best able to

speak from experience and cultured taste to give their views of the subject.

A method adopted by Mr. Spiller in his early adventures in portraiture might in such case be tried with advantage as a means of reducing trouble; we refer to his mode of placing the sitter and camera a measured distance apart. If the plan of working to scale were adopted, opticians would not find it difficult to give the specific distances a lens would require to give images one-ninth, one-fifteenth, or one-twenty-fifth of the size of nature, and so save trouble to the photographer.

Without dogmatizing on this subject, we cannot but feel that the rendering of just proportion will confer on photographic portraiture an interest and a value which at present it fails to possess. Let us know that the portrait gives an impression of the complete man. Let the portraits of a growing family present an idea of that growth, and so tell the physical story of their lives from year to year. A series of such photographs of a growing life, dated and annotated, would form an important element in the history of an individual, of peculiar and pleasant interest to all the family.

THE SPECTROSCOPE AND PHOTOGRAPHY.

THE correspondence on the subject in the leading daily journal has been continued by an anonymous correspondent, who does not add much to elucidate the subject. When a controversy is carried on between A and B, nothing especial is gained by X exclaiming "I agree with B." Here is the letter addressed to the Editor of the *Times* :—

"Sir,—Having made a series of carefully arranged experiments at intervals extending over some years, in order to ascertain the action of the blue, yellow, and red rays upon sensitized surfaces of various kinds and colours, I can most heartily endorse the statements of Mr. W. J. Stillman in the *Times* of the 21st.

"With regard to coloured films, either on Daguerreotype plates or glass or paper, and whether stained by impalpable powders or the colours made chemically in the film—say, for example, of red, orange, or green—the result is that the impression has the appearance of being acted upon by the corresponding rays of colour, but is, in fact, merely an artificial substitution, upon which sometimes it happens that the light and the chemicals act as a mordant, but is no evidence whatever of the co-adaptation of the sensitized surface to the nature of the red, orange, or green rays of colour.

"For scientific data nothing short of a definite chromatic reproduction of the colour—say, of the solar spectrum—upon a homogeneous sensitized surface will have the slightest value in the minds of practical men.—I am, sir, yours, &c.,
AN OLD PHOTOGRAPHER."

PORTRAITS WITH MOTTO MARGINS, AND HOW TO MAKE THEM.

BY CHAS. H. EVANS.

IN the dull season of the year a little novelty will often bring trade.

The thing about to be described is one which has taken capitally with my customers, and therefore I recommend it, as it is easy and cheap to do, and, when tastefully done, recommends itself. The idea is to send the season's greetings with a photograph of the sender in the centre, and the *modus operandi* is as follows.

Take a sheet of cartridge paper, 25 by 20 (I used tinted crayon papers at first, but found that the cheap cartridge paper is equally as good, at one-fourth the cost), tack it on a flat board a few inches larger than the paper each way; then take some branches of holly, mistletoe, or ivy, and arrange this around the edge of the paper, fixing it in

its place with a few tacks or pins. Now draw in the centre of the paper a line, either dome-shaped or oval, and arrange as before, in the line, some more green stuff; then take a soft conté crayon, and in the space between the outer and inner green strip do the greeting—A Merry Christmas, or the Compliments of the Season, or any other. I prefer using a crayon for doing the lettering, as when done it is a dead black, and as long as you preserve the shape of the letters, the rougher it is done the more rustic it looks. When this is done, then stick it up and photograph it.

After the negative is made and varnished, it is necessary to make a mask for the inside of the centre lot of evergreen. It may be done by printing a light impression on sensitive paper, and cutting out carefully the inside space of all, and sticking it on the outside of the negative, or by stopping out on the film side with black varnish. The latter plan is, to my mind, too troublesome. When, however, the centre is masked by either the above methods, the negative is then ready for use. Print a vignette about the size to suit the mask on the motto negative, and, when printed, place the picture on the motto negative, having taken care that it shall be in proper position, and protected by the mask. Print the margin, but not quite so deep as the portrait, and it is finished. If, however, you want to do without vignetting, the better plan is not to make a centre piece of green stuff, and to print the portrait in an oval or cushion shape and stick a disc that corresponds on the film side of, the motto negative.

PHOTOGRAPHING BRASSES IN CHURCHES.

BY WILLIAM BROOKS.

AT the last Technical Meeting of the South London Photographic Society, held at the Society of Arts, John Street, Adelphi, I briefly introduced this subject, and I have no doubt that many, owing to its brevity, did not thoroughly understand the true meaning of my communication, and, therefore, think it may be of interest to photographers, both amateur and professional, the latter especially, as it could be made a source of profit. I am indebted to Mr. Tom Brine, of Canterbury, for the idea, and by whose permission I introduced it at the Society.

I remember that I attended a lecture some ten or twelve years ago, at St. John's Hall, Penzance, on the subject of church brasses, and it was very interesting. The lecture was illustrated by a series of rubbings of all sizes: some were, I should think, nearly ten feet in length, and very interesting they were. Getting these rubbings involves an immense amount of labour, especially if of any size. I dare say most of my readers know and have seen these brasses in churches; for those who do not I will just give a brief description.

It was the practice for many centuries, when persons were buried in the body of the church, to mark the place of interment by letting a large engraved brass plate, *deeply cut* with likeness of the party interred, in full costume as worn in earth-life; and I have no doubt, in many instances, as a matter of portraiture, they are correct. As a rule, they generally bear an inscription setting forth the name of the party, his or her rank, and station in life; and sometimes these inscriptions are very quaint indeed. These brasses or inscribed plates are generally to be found in or near the chancels of churches, and are mostly covered up with coconut matting; and unless one goes and looks expressly, they pass observation. When man and wife are buried together, and have had issue, the family of sons and daughters, are indicated by having figures of them also engraved—the sons by the side of the father, and the daughters by the side of the mother, and by the costumes (even if the brass has been damaged, or the inscriptions removed or worn away) the date can be arrived at.

In most old country churches these brasses are to be

found; in some I have seen the pavement covered with them, dating back several centuries, and in a good state of preservation, and quite works of art in their way, and anyone almost fond of these curiosities can be allowed to take a rubbing by tipping the sexton, or pew-opener, or whoever may be in charge. To get a rubbing is not very difficult; it only requires a little care.

The best paper for the purpose is white lining paper; it can be obtained at almost any shop where paper hangings are sold, at one shilling per piece (containing twelve yards), which is not very expensive; and the other article which is required is heel-ball, used by boot and shoemakers to give the black gloss to the edges of the soles and round the heels of boots; it can be obtained at any leather-sellers' or shoemakers; it is a waxy-looking substance, and is made in several degrees of hardness. It is best to get a few cakes of each; the softer does better for the heavy blacks, and the harder kind does better for the fine lines, if any, as it does not clog so much as the softer kind.

The mode of procedure is this: well sweep and dust the brass very carefully, for if any grit is under the paper it will cause a lot of annoyance, and will work unpleasantly; when this is done, cut off a piece of the white paper about one foot longer at top and bottom than the brass, lay it down (taking care to keep it well in the centre), and lay some heavy books (plenty are generally to be found about the church) at the top and bottom, to keep the paper in its place so as not to shift, and by passing the fingers over the paper so as to feel the outlines, go round it lightly at first with a piece of the hard kind of heel ball, so as to obtain the exact position of the figure or figures; when this is done, proceed to rub all over vigorously with the flat part of the cake until all the image is fairly visible; the heavy parts can then be gone over with the softer kind of heel ball, and using only the harder kind for fine working and delicate work, and the thing is complete. It can then be rolled up, and if any more be wanted, another can be proceeded with.

This is a capital warm job for cold weather, especially if plenty of elbow grease is used. This kind of thing can be done when photography in the winter months is at a standstill.

The rubbing so obtained is a negative, and not a positive, as the engraved or sunk parts of the rubbing are represented by white lines, and the flat or unengraved parts, representing whites in the rubbing, are intense black, whereas if the brass were new it could be seen as a positive; now the photographic part of the business steps in, and sets matters right.

Before any attempt is made at photographing the said rubbing, it must be carefully looked over and corrected, as it will be found that in the damaged parts of the original brass, where there has been no resistance, the paper has not taken the heel ball, and remains white; all these defects can be remedied by laying the rubbing out on a large table, and placing a piece of glass or hard smooth substance under, and just going over it with the heel ball again, taking care not to destroy or alter the drawing; or it can be retouched with some black pigment and brush. The rubbing is then placed flat on the wall and photographed, and the result will be a *positive*, and from this positive can be made any size negative required in the camera in the ordinary way by transmitted light: being a black-and-white subject, it can be enlarged to any extent without being offensive as regards texture. Should copies be required the exact size of the original, the rubbing can be used as a negative direct, and printed in either carbon or silver (I have seen some brasses not larger than one's hand). It has also occurred to me that this system might be made use of in various ways; for instance, in churchyards we find quaint inscriptions on tombstones, and inside of churches we find quaint inscriptions on monumental tablets; and at times photographers are called upon to photograph

monuments in churchyards of that red kind of granite so often seen with black, sometimes gold letters, which sometimes photographs so as not to be readable, and, unless all the inscription can be read, it never gives satisfaction to the client. Now a rubbing of the inscription can be readily made by the above means, and a negative made, and the inscription printed in, and a perfect whole is obtained, which does credit to the photographer, and gives satisfaction to all parties concerned; and I have no doubt that in many other ways this system may be utilised to obtain photographic representations that could not be obtained by ordinary means.

A PLEA FOR STANDARD SIZES IN PORTRAITURE.

BY JOHN SPILLER, F.C.S.*

In proceeding lately to arrange a series of scientific celebrities in my photographic album, I am met by a serious obstacle arising from the want of uniformity in the size of the heads, and it often becomes impossible to place side by side those whose official relations would otherwise dictate such a course.

Thus the head of Professor Tyndall, measuring in the photographic portrait nearly one and three-quarter inches, does not look well when shown alongside that of Faraday, taken on a much smaller scale (seven-eighths of an inch only); and the fine little portrait of Sir David Brewster, with head measuring barely five-eighths of an inch, appears altogether diminutive in such comparison. Even in the professed scientific series of the self-same photographer there is often the widest range in the scale of representation, and those which should go together cannot very well be placed in juxtaposition.

In "Men of Mark," this point appears to have been attended to with manifest advantage, and the frames of Woodburytype portraits shown at our recent Exhibitions have always borne this character of uniformity, and give a feeling of satisfaction which is, as a rule, wanting in the frames shown by many of our leading portraitists. The splendid series of Adam-Saloman's works shown in the International Exhibition of Paris, 1867, had likewise this charm of being all represented on the same uniform scale, and it was then possible to determine whether fully-grown or younger persons had come under the treatment of the eminent artist.

In many photographic establishments, arrangements are adopted which practically secure this very desirable uniformity in the scale of production, and special instructions on this head are no doubt attended to; but in looking over my albums, I am surprised to find that in very many instances of professional portraiture the members of a family have been taken without any regard to this common rule, so that children are made to appear bigger than their parents, and between wife and husband there is again a disproportion not founded upon fact.

It would be easy to adopt a rule for common acceptance, and the matter seems to me quite to justify a discussion of the subject, or even a conference, whereby a general agreement might be arrived at, so that for certain standard sizes—cabinets, cartes, &c.—a scale of uniformity should be the rule.

In measuring a large series of portraits, I find, for instance, that Bergamasco's cabinet bust vignette of H.R.H. the Princess of Wales appears to be taken on a scale of one-eighth natural size; whereas Reutlinger's famous series of actresses, and most of the American cabinets, are taken larger than this, or about one-sixth natural size. Then for carte portraits and vignettes all sizes are to be found, from one-sixth downwards; some have been printed from larger-sized plates, as doubtless those of Professor Tyndall and of the late Sir Francis Grant, whose head measurement on the photograph is one and five-eighths inches—much too large to look well in a general series where one inch is, perhaps, the average measurement.

Many years ago, when taking the portraits in my home

circle, I adopted a scale of one-tenth natural size, and I maintained that such a series, showing true natural relation, offers much to compensate for the manifest deficiency in artistic treatment which these pictures exhibit. They stand good in any arrangement, page after page showing elders and youngsters in family groups, and each of the *proper size*.

And now, finally, I have a confession to make, whereby it will appear that this system of working was most convenient to me, for I had when a boy only a quarter-plate French lens, the visual and chemical foci of which were not coincident, and therefore, to save trouble and easily secure the correct definition, I made a point of placing the sitter at a known distance from the camera (ascertained by a measuring rod or cord), and then screwing out the lens to a notch or scratch on the tube. In this way, not only was uniformity of scale secured, but I was always sure of getting the right focus—a matter of some anxiety with all workers in 1854, who did not happen to possess either a Ross or Voigtlander portrait lens.

COLLOTYPES ON ZINC PLATES.

BY PROF. J. HUSNIK.*

THE first attempts in the collotype process were made on metal plates, and the adhesion of the film was generally effected by the oxidation of the metallic surface. Since Albert introduced the use of glass plates, that of metal as a support for the colloid films has been entirely neglected, for it was not possible to obtain such even and firm films on metal plates as on plane polished glass plates. Obernetter has succeeded in overcoming the difficulties that attended the uneven surface of metal plates, and has for some time practised a system of collotype in which he uses, as supports, zinc plates as thin as paper. Although he himself now also lays the chromated gelatine film on a glass plate, his former method is found to be of very great efficiency, and it is employed with advantage not only by Albert himself—more especially in his large size pictures—but also by several other houses. Such thin plates of zinc are used for glazing printing paper, and are found in the market with a perfectly even and almost perfectly polished surface. This circumstance considerably facilitates the manipulation, for it is only necessary to clear off with emery paper any grease or dirt that may happen to be on the plate, when the preparation can at once be proceeded with.

First Preparation of the Zinc Plate.—When the plate has been rubbed down as above described, it must be dusted with a short brush, and then once or twice washed first with pure water, and then with a three per cent. solution of chromic acid. The acid forms, with the metal of the plate, zinc chromate, which remains as a yellow coat attached to the surface, and this causes the perfect adhesion of the gelatine to the metal. After the solution of chromic acid has been allowed to drain off for some minutes, the plate, while still wet, is rinsed several times with pure water, and, when thus thoroughly moistened, it is coated with a filtered solution of one part gelatine in twenty parts water mixed with four parts spirit. The plate must now be held over a hot stove plate, or over a flame, in order to prevent the gelatine from setting too rapidly, and so that the solution may be distributed as evenly as possible. Afterwards the solution is drained off, and dried in a drying oven. Obernetter and Albert allow the zinc plates to dry in a horizontal position at a temperature of from 35° to 45° R.

My own experience is, that better results and more even films are obtained by suspending the plate at the centre over a square stick, placed horizontally, the ends hanging down on each side somewhat in the form of an arch, and allowing it to dry in that position. It is true that the film will flow for a few seconds longer from the top of the arch towards the ends; but if the temperature of the oven be

kept at from 50° to 55° R., the upper part of the plate will dry quicker than the lower, and this unequal drying will adjust the evenness of the film, so that it possesses everywhere the same thickness. For this first preparation, however, the position of the plate during drying is of no importance, as only a thin film is left on it; of so much the greater consequence is it in the succeeding operation.

Second Preparation.—The first film is not in the least degree sensitive to light, for no chromic salt was added to the gelatine; its object is to produce adhesion between the chromated gelatine film and the zinc plate. It would be quite possible to mix the first layer of gelatine with the chromic salts, and to produce it at once of the required thickness; but the results obtained are in every way better when the films are employed. The first layer is tanned by means of the zinc chromate and the other products of the decomposition—chromium chromate, for instance—and this tanning action penetrates the entire thickness of the film, causing dark spots in the prints; but a second layer combines with the first, so that both adhere firmly, and irreproachable prints are produced.

For the second layer, a hot solution of 100 parts in gelatine in 1600 parts water must be prepared, and mixed with 20 to 25 parts of some bichromate salt (ammonium bichromate is most sensitive) and one part chrome-alum; the latter substance must only be added slowly, or it will cause coagulation. The zinc plate is now placed on a horizontal table with the already prepared surface uppermost, and the solution is poured on it, and spread over it briskly with a brush; more solution is again poured on and rapidly drained off, so that all bubbles may be removed. After the greater part is thus drained off, the plate is hung up in the form of a bow in the drying oven at a temperature which must not exceed 45° R., nor fall below 35° R. Albert and Obernetter, before drying the film, warm it slightly, and then lay the plate on the top of a flat vessel covered with a horizontal metal sheet; ice-cold water is made to flow through this vessel, which keeps the metal-plate cold. In this position the gelatine sets evenly before it has time to run into the depressions of the plate; the plate is then dried in the oven at a temperature of from 40° to 50° R. As the first layer absorbs a portion of the water, the second layer is no longer liquid at the above-mentioned temperature, and dries very evenly. For my own part, however, I prefer drying by suspension, as I have already described.

When the second preparation is completed and the film thoroughly dried, the plate is exposed under a negative in the same way as an ordinary glass plate. The process of exposure is much facilitated by the zinc plate being so thin that it can be accurately pressed on to any kind of negative, whether it has a plane or a curved surface. In copying also, just as in printing on paper, the plate can be raised and bent over so as to give an opportunity for examining how the action is proceeding. So soon as the half-tones make their appearance, the exposure must be interrupted, and the plate developed with water.

When a print is to be taken from the plate, the latter must be carefully wiped on both sides, and more especially on the reverse, so that no grain of sand or dust remains adhering to it, for any such impurity will, in the press, be driven into the zinc, so that it cannot be used a second time. A perfectly clean lithographic stone is now coated with thick lithographers' varnish, the reverse side of the plate laid on it, and the whole pulled in the press; the plate will then adhere to the stone, and form a support for it. We are now in a position to proceed to inking the plate and taking a print from it. The rollers best adapted for collotype printing are those found at the establishment of Romäue Falbot, 68, August Strasse, Berlin. They are small glue rollers with only one handle; they do not tire the printer, and allow the work to be proceeded with rapidly.

* Photographisches Wochenblatt.

Films prepared by this method possess extraordinary durability; the plates are only worn out after very long use in the press, when the upper surface of the film begins to deteriorate. The low price of the materials employed permits of large plates being produced very cheaply, and there is no occasion to fear their cracking as with glass plates. If great care has been taken in printing, the zinc plate can be used again; it is only necessary to dissolve off the gelatine in a hot solution of alkali, and to rub down the plate afresh with emery paper. Albert has produced collotypes, by this method, a metre and more in length; the copy of the picture "Lohengrin's Farewell," was printed for the Art Society of Vienna for zinc plates only.

By the side, however, of the advantages that this process possesses over that with glass plates, it has one prominent defect: it sometimes happens that after the plate has been printed from continuously for four or five days small spots of oxide make their appearance, and the films become altered so that in these spots, too much ink is taken up. Before printing, therefore, the plate must be carefully gone over, and those spots where they occur in the light parts must be carefully wiped away. On this account it becomes necessary to use up the plate as quickly as possible, and to keep it perfectly dry while not in use, for in a dry state the alteration will not take place.

For moistening the plate, I recommend the well-known mixture of glycerine, water, common salt, and ammonia, and to employ it in a concentrated form; when the plate is once moistened with this mixture ten to fifteen prints may be taken from it, and the time that is usually occupied in wetting the plate after every pull can in this way be saved. With thicker films even fifty to eighty prints may be taken without a fresh moistening, but such films have not so fine a grain, and are liable to tearing.

On the other hand, this process affords the means of working with a quick running press and endless paper, for the printing plate can be bent round and fastened to the cylinder. The inking and moistening can be effected by several rollers on one side of the cylinder, while the printing takes place on the other side, when the endless paper comes into contact with the film. Albert has long ago come to the determination to have machines of this kind constructed, but is waiting until he can quite get rid of the spots of oxide which so often make their appearance. There certainly are means for, at any rate, weakening the effect of these spots, but none, so far as I know, that will quite get rid of them.

The addition of chrome-alum, as I have above recommended, has a considerable influence in this direction, and so has the moistening with the solution of glycerine and ammonia. If each spot be stippled with a fine brush dipped in a concentrated solution of ammonium oxalate, the spots will vanish for a time, but return again the next day, when they must be again treated in the same manner.

MASON'S INSTANTANEOUS DROP.

BY O. G. MASON.*

THE subject of instantaneous photography having recently claimed our attention in connection with emulsion work, and appearing to be on the verge of a larger and more practical field of operation, through this comparatively new process, I have thought that it might be interesting to some of the members present to review the methods which have hitherto been in use for this class of work, so far as the mechanical construction of the instantaneous drop or shutter is concerned.

Most of those who have practised in this department of our professional work are aware that many and various devices have been used to accomplish the result sought.

First, we have the ordinary and commonly used "drop,"

a thin piece of wood or metal so arranged before the lens as to shut out all light when elevated, and held in place by a catch or spring, the liberating of which allows the slide to fall, and in its passage across the field of the lens gives exposure to light through square or circular openings cut for the purpose, and again shutting out the light as it comes to rest at the bottom of the guides, as may be seen by the one which I now exhibit. When I had the device constructed, some twenty years ago, I knew of no better method. A year later, in my first attempts in photographing the sun, I found that there were many and serious defects in it, which were partially remedied by springs to accelerate the motion, and cushions to break the force of the concussion when the falling slide was arrested.

For landscapes and other classes of work in which were greater variety of objects possessing gradations of light from deep shadows to the brilliant glare of bright sunshine, the apparatus was yet very far from satisfactory; and to still further improve and add to its utility, I have devised and constructed the one which I now exhibit.

You will perceive that I have retained the main features of the old, before-described "drop." The modifications have been made in such direction as admit of easy and inexpensive construction, while the real value of the apparatus is increased many fold.

From the central portion of the slide, as you see, I have removed nearly one-third of the entire length, leaving just sufficient wood on the two edges to give the proper strength. At each end of this opening I fasten light guides or slides, so made as to receive and hold in position rectangular pieces of black cardboard, which we may designate diaphragms. A series of such pieces, through which any desired size or form of opening may be made, enables the operator to most completely control the exposure. By their judicious use he may increase or decrease the amount of light entering the lens from any portion of his subject.*

By the use of the rubber spring, so fastened to the body and slide of the apparatus as to be very easily detached or exchanged for others stronger or weaker merely by the turn of a screw, greater latitude to the speed of the slide for increasing or diminishing the time of exposure is given, which is also under complete control by increasing or diminishing the size of opening in the diaphragms. The arrangement of the spring together with the clamping screw for attaching the apparatus to the mounting of the lens, are such that the slide works most admirably in a horizontal position, in which position its peculiarities are best utilized.

With a diaphragm having a triangular shaped opening, with the apex of the opening upward, a short exposure may be given to the sky; and by reversing its position, a less exposure may be given to the foreground, for producing the effects generally termed "moonlight."

While an unbroken horizon or ocean view may be admirably treated by using a diaphragm with opening somewhat like a compressed Gothic capital letter T, a little practice will enable the operator to select forms of dia-

* The Editor of the *Bulletin* has illustrated the front side of the apparatus, and two detached diaphragms, in order that the reader may more fully understand its peculiar features.—O. G. MASON.

* Read before the Photographic Section of the American Institute.

phragms suitable for any subject. The diaphragms are very easily exchanged by pulling the slide a little past the position it occupies when ready for making an exposure, and they are held in position by the slide guides, from between which the opposite end does not entirely pass after the exposure is made.

The slide is held in proper position for focussing by a pin in the block or body portion of apparatus attached to lens mounting.

The slide is held in position with the rubber spring, extended ready for exposure, and a delicate wire spring; by a light pull upon a cord attached to this the exposure is made. By liberating the rubber spring, loosening the clamp screw, and turning the apparatus into a vertical position, it may be used like the ordinary drop slide, yet retaining the advantages of the variable diaphragms in cases when one side of the view is more brilliantly illuminated, or where one side or end of the scene has a higher horizon than the other.

Proceedings of Societies.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of this Society was held on Monday, the 6th inst., at Bradford, Mr. JOHN HOWARTH, the new President, occupying the chair. There was a large attendance of members.

The CHAIRMAN congratulated the Society on its flourishing condition in the present dull times; it demonstrated that the members, like himself, had its interest at heart. He trusted that some arrangement would be made for a larger supply of material for discussion at the Society's meetings, and that all the members would work towards one end, so that the Society might take a leading place amongst kindred institutions.

Mr. Davis was elected a member.

Mr. J. CROSTHWAITE then read a paper on "Art in Photography" (see page 50).

Mr. E. WORMALD said the writer justly remarked that part of a man's art-education must be obtained by studying and comparing the works of other men. Such men as Michael Angelo and Raffaele were not above learning from others, even inferior to themselves; how much more, then, they, weaker men, had need to follow in their steps! If a man studied good models it would necessarily lead him to a better knowledge of art. He was of opinion that photographic art, in some men's hands, had reached a very high degree of excellence; and he had seen photographs which, as studies of light and shade, were equal to the best works of some of the greatest painters.

Mr. S. SACHS was of opinion that it was imperatively the duty of every photographer to make himself familiar with art, as much as it was to learn to expose and develop a plate. Excellent manipulation was not necessarily good photography; to produce fine art work a considerable amount of brain power, as well as technical excellence, was required. In old times a good chemist was considered a good photographer; now the public judged mainly of a man by the amount of artistic ability displayed in his work.

The CHAIRMAN thought most men commencing photography had some art enthusiasm, and probably had some incipient feeling that only required developing and educating. No one should be discouraged by seeing the splendid productions of some of the masters of the art, but rather consider it a part of his education. He thought that art education was necessary, and believed that a society was admirably fulfilling its duties in endeavouring to smooth the path for the earnest student.

Mr. W. T. BURROW endorsed the sentiments expressed in the paper as to the value of studying carefully the art productions of all ages, as by so doing anyone would doubtless achieve some degree of success.

Mr. E. GREAVES said the public required art education as much as the photographer; they had not the requisite appreciation of good work. Almost every photographer would have had experience of that by the number of rejected proofs which were exceedingly good, and the selection of indifferent ones. All this was very discouraging to anyone desirous of doing really meritorious work. He thought the public were to blame for the large amount of the poor work executed; when good work was placed before them they would not have it.

A vote of thanks was then given Mr. Crosthwaite for his paper.

Mr. WORMALD inquired whether the system of warming by hot water pipes or hot air produced the greatest condensation of moisture on the glass of a studio.

Mr. HAWORTH replied that the condensation of moisture on the inside of the glass of a room was caused by cold outside; and in the case of warming by hot water, the air in the room being charged with moisture it condensed on the glass, was evaporated and re-condensed, and thus the room remained constantly wet, the same air being kept in the room. If the room were warmed by hot air, the case was altogether different, as the constant influx of heated air forced out the same quantity from the room, which carried away the moisture with it, and thereby prevented its condensation. As he had previously pointed out, in a paper read before the Society, a wash leather or linen cloth hung in a room not warmed by hot air, would be found moist or damp, and glasses cleaned only a short time before being wanted, would be found to have a film of moisture on their surfaces. He (Mr. Howarth) could not conceive how a photographer could work with any degree of comfort in rooms warmed by other than the hot air system.

The meeting then became conversational, and was shortly afterwards adjourned.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

A MEETING was held in New York, November 5th, 1878, the President, H. J. NEWTON, in the chair.

The minutes of the last meeting were read and corrected, and, as corrected, approved.

The SECRETARY exhibited a lot of prints and negatives sent by Mr. R. E. Atkinson, of Troy, N.Y., for competition for Mr. Newton's prizes, but as the terms restricted the area to within twenty-five miles of the City Hall, he was outside the competing field. As there was no mark on the package it was necessary to open it in order to know to whom it should be returned. I took the liberty of opening it in the presence of the President, and we thought it might be well to show them to the Section; so I wrote to him asking if we might do so, and in his reply he says that they were not made especially for the purpose of competition, but were merely selected from his ordinary work. It struck me that these negatives, with the amount of finish put on them that is put on negatives in New York, would compare favourably with first-class gallery work.

Mr. NEWTON: I think they are much better than a majority of negatives that are elaborately retouched. The generally expressed opinion was that as plain work it was exceedingly fine.

Mr. WARREN exhibited to the Section some burnt-in photographs on glass and china, and explained the *modus operandi*, and the different metals used to produce the various colours.

Mr. MASON exhibited to the Section several instantaneous drops, and explained the working of those used in the production of the pictures shown by the President as follows (see page 58).

After the paper Mr. NEWTON said: At our last meeting there was some instantaneous work exhibited, made from dry emulsion plates. Since then I have been trying wet emulsion. I took some portrait emulsion and went last Thursday over to Mr. Mason's studio, at Bellevue Hospital, with it, and we made several exposures, but failed to get satisfactory pictures on account of over-exposure. The next day I went over and took a less sensitive emulsion, between thirteen and fourteen months' old, which required about double the time of exposure, and we succeeded in getting some very beautiful negatives. I meant to have brought some of the negatives with me tonight, but I have only brought the prints from them. I forgot to take the negatives.

The PRESIDENT exhibited several prints, which showed full exposure, illustrating the character of the negatives.

Dr HIGGINS: The remarks I was about to offer were in relation to the employment of iron by photographers; its employment is universal almost, and almost entirely for the purpose of development. The salt that is used, commonly called copperas, also known by the name of sulphate of iron, and chemically known under the symbolic form of $\text{Fe SO}_4 + 7\text{H}_2\text{O}$ is a salt which we term the ferrous sulphate of iron. Iron, however, is multiple in its combinations—that is, it combines with acids in more proportions than one; in the combination just given it is bivalent. In another combination it is quadrivalent, although frequently thought to be trivalent. In this case we have Fe_2 joined with 3SO_4 , and represented symbolically by $\text{Fe}_2 3\text{SO}_4$. The salt is then termed a ferric salt. Now between these two salts we have another salt, and it is of that I would speak. This other salt is represented symbolically by $2\text{Fe}_2 5\text{SO}_4$, and is known pharmaceutically under the name of Monsell's solution, and is a sub-sul-

phate of iron. If one ounce of this solution, as purchased from the druggist under the name of liquor ferri sub-sulphate, is mixed with a pint of water, such solution answers the purpose most admirably, and better than anything I have used, of decreasing the intensity of the negative, contrary entirely to what the properly termed ferrous sulphate of iron does. There have been very many modes offered to the profession of decreasing the intensity of the negative. All of them are objectionable in some particular. When flowed upon a negative that is too intense, it will do its work slowly, gradually, and surely, with no fault of any kind, and will keep on reducing it, if left on long enough, until the entire negative disappears.

Mr. MASON: Do you use the solution before or after fixing?

Dr. HIGGINS: Either one; also upon a plate that has been fixed, dried, and put away, but not varnished.

Mr. CHAPMAN asked if this was applicable to a negative that had been intensified with mercury.

Dr. HIGGINS: I see no reason why it should not be, but have not tried it. By request of the members the Doctor showed the experiment, as follows:—A small emulsion plate was placed in contact with a negative in a printing-frame, and exposed to light from an ordinary gas jet for one second of time, the development resulting in a very intense negative. The plate was divided with a diamond for purpose of comparison, and one-half thereof reduced slowly, and entirely at option, to almost disappearance.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will take place on Thursday next, February 6th, at the rooms of the Society of Arts, Adelphi, when Mr. J. Hazard will read a paper on "Gelatine Plates in the Studio," and Mr. G. Willis, Junr., will give a demonstration of his new platinum process.—H. GARRETT COCKING, Hon Sec., High Street, Lee, S.E.

COMBINATION GROUP OF LORD LORNE AND HIS WIFE.—A Canadian correspondent of the *Times* states that recently the Princess Louise, accompanied by Lady Macnamara, paid a visit to Mr. Topley's photographic studio, and sat for a portrait which is to form part of a composition picture to be prepared by Mr. Notman, of Montreal.

HARD TIMES.—A correspondent writes as follows:—"Noticing a word or two in the *News* relative to hard times, I recollect some two or three years ago, at Forest Hill, a man named D. Brown, carrying on the business of a photographer and chimney-sweep combined, one side of his card containing the announcement of one business, and the other side the other. Truly a veritable worker in carbon!"

ARTISTIC COPYRIGHT.—We understand that the Royal Academy have for some time been occupied with the question of artistic copyright. Feeling that the recommendations in the report of the Royal Commissioners with regard to the copyright in paintings and drawings are antagonistic to the interests of all artists, and, indeed, also to those of the public, a committee was appointed last year to inquire into the whole matter. This committee has, we believe, just presented to the council a report, which, if its conclusions meet with the approval of the general body, will no doubt be forwarded to the Government, and every endeavour made to prevent those recommendations of the commissioners which are considered injurious to the interests of art being incorporated in the forthcoming Bill.—*Academy.*

To Correspondents.

C. J. HALL.—We have published from time to time many articles on photographing on wood; but it is difficult to say which is best. You ask for one with a tough film, suitable for wood-engraving. Our own conception of what is best suitable for the engraver is quite opposed to a tough film, which would be apt to tear in engraving. It seems to us that the film should be—if a film be used at all—as thin and short or rotten as possible—practically a powdery layer, through which the graver would pass without being torn or disturbed, merely taking the line of cut. The best plan, in our view, of getting a photograph on the block for the graver is first to produce a photo-lithographic transfer, and so transfer the image in a fatty ink to the wood, as it would be to the stone for lithographic printing. If a film be used, the collodio-chloride process would answer well.

CARBON LANTERN.—We should think the liquid aniline colours would answer best for colouring carbon slides. Probably a coating of dilute albumen would make them take the colours easily.

W. W.—Genuine gold leaf is, we believe, in most cases, used for gilding the edges of cards, and no fear need in such case be entertained as to gold leaf injuring a photograph. We never heard of bronze powder being used for such a purpose, nor do we see that it could be so used. It would be ineffective, and detected at once. For common work in what is termed "gilding," a common leaf is sometimes used called "Dutch metal," and, being in leaf form, it might be used for edge-gilding; but it would be detected by its colour at once if submitted to a practised eye. Examine a parcel—say a score—of the cards, so as to get a sufficient surface of edges. As a rule, the Dutch metal is light coloured and brassy. What alloy of metal is used in making Dutch metal leaf we do not know, and hence we cannot with certainty say whether there would be risk to the photograph in its use. 2. We know nothing of the Albion Albumenizing Company except their old address. We, like you, look amongst the advertisements in the *Year-Book* for the address, and when we don't find it, fear something has happened. Their address used to be Brackenbury Road, Shepherd's Bush.

W. S. (Reading)—There is some difficulty in answering your question satisfactorily. It used, in the old time of dry-plates, to be regarded as a recognised characteristic of dry-plates that they were specially insensitive to imperfectly lighted subjects, and therefore undesirable for use in dull light. They were not, therefore, thought useful often for interiors. The modern rapid emulsion plates are, on the contrary, relatively more sensitive in dull light than wet plates. See a communication by Mr. Henry Cooper in our last issue. Here, then, is the difficulty in advising you. The best plates for an interior are the extra sensitive gelatine plates. But you require something suitable to unaccustomed hands. Probably, your best plan will be to purchase extra sensitive gelatine plates, and use great care in accurately carrying out the instructions. Such extreme care will often be found an equivalent for practice. You must bear in mind that the dark-room used for developing and for unpacking plates and putting them into the dark slide must be better protected from every trace of actinic light than is necessary for wet plate work. Use great care and precision in following out the instructions for development. You will find many hints in articles in our *Year-Book* just issued.

THE LUXOGRAPH CONTROVERSY.—Notwithstanding our announcement that we could not insert any more letters on this subject, we have received further communications from S. Lombardi and Messrs. Alder and Clarke. S. Lombardi "humbly begs the favour of a short reply as a foreigner," a form of appeal we do not like to resist, and therefore give the substance of his reply. He says the first, second, and third paragraphs of Mr. Faulkner's letter have already been proved "incorrect, erroneous, and false." And in this he is so, why need anything more be said about it? When a thing is proved, there is an end, unless we adopt Dogberry's way of speaking: "Masters, it is already proved that . . . and it will go near to be thought so shortly." He proceeds to repeat the remark, already often reiterated, that Mr. Gregson and other witnesses testify to Mr. Faulkner's eulogistic expressions at the demonstration and that this was all the testimonial stated. In reference to Mr. Faulkner's allegation that he (S. Lombardi) is a partner in the Luxograph Company, he states that Messrs. Alder and Clarke simply rent rooms in his establishment, and that he bought and paid full price for his apparatus; and his testimonial was spontaneously given. S. Lombardi then reverts to the subject of Mr. Faulkner's method of producing backgrounds. But as this subject has no earthly connection with the question in discussion, we cannot devote space to it now. Whatever interest it had is long since past. Messrs. Alder and Clarke's letter chiefly consists in reiterating what has already been said. They repeat a portion of Mr. Gregson's letter. They point out that Mr. Faulkner admits offering £15 15s., a testimonial, and some specimens for the apparatus; and they also state that S. Lombardi is not a partner in the company. They conclude by affirming the *bona fides* of all their testimonials, and by stating that Mr. Faulkner, and not themselves, commenced the squabble into which Mr. Faulkner says he has been drawn. We have already devoted more space to the discussion than is fair to our readers; and we must definitely state that any further discussion must be conducted, if desired, in the columns devoted to business announcements.

L. CAMILLERI.—The double sulphate of iron and ammonia may be purchased of most photographic chemists, or it may be easily prepared. Take two ounces of sulphate of iron and one ounce of sulphate of ammonia; dissolve in four ounces of hot water, and set aside in a warm place, or place over a water bath to evaporate and crystallize. Or the solution may be diluted, and, with the proper proportion of acetic acid added, used at once for development.

CHARLES JONES.—The paper to which you refer is contained in the *Photographic News* for June 23rd and 30th, 1876, but not in any of the *Year-Books*. The back number of the Society's *Journal* may be doubtless obtained of the publisher; but is not kept by our publishers.

The Photographic News, February 7, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

DULL WEATHER AND SENSITIVE PLATES—PAINTERS AND PHOTOGRAPHERS, AND THEIR TREATMENT BY THE COPYRIGHT COMMISSIONERS.

Dull Weather and Sensitive Plates.—The man who looks after the sunshine at Greenwich Observatory has had very little to do lately. We doubt whether the Astronomer-Royal will report a single hour's sunshine during the week ending February the first, and if matters don't improve we may expect some ultra-liberal member, as soon as Parliament meets, proposing the reduction of the Estimates by that man's salary. We made some remarks, last week, upon the disadvantages of cold weather from a photographer's point of view, but the dull heavy period recently experienced is far worse to him than the cold. Fancy a printer required to furnish a gross of copies in a week, and he had such a week as the last to do them in. No wonder we have been making such a fuss about the electric light lately. We are so thankful for light of some kind this leaden weather that photographers have been driven to employ gas for making transparencies and multiplying negatives. Nay, in the absence of the sun, we see that some enterprising spirit has been making use of the moon. At the last meeting of the Manchester Photographic Society Mr. James Young exhibited a transparency which he had printed by the light of the moon in sixty seconds one January evening. The plate, he informed his audience, was prepared with gelatine emulsion, and exposed in contact with a negative in the ordinary way. It would have been interesting if Mr. Young had continued the experiment to see if the same sixty seconds' exposure would have given a picture upon a collodio-bromide film. As Mr. Alfred Brothers very truly remarked, it was a subject that had its importance, this moonlight photography, for it was the first instance, he believed, in which the moon had been employed for printing in this fashion. There can be little doubt as to the extreme sensitiveness of gelatine in conjunction with bromide of silver, and it seems more than likely that we shall see it introduced into the photographic studio for portraiture. In some cases its sensitiveness is reported to be not less than four times that of an ordinary wet plate, or, in other words, a four-second exposure with a gelatino-bromide film gives as good a picture as sixteen seconds with an ordinary wet collodion plate. This, no doubt, is under the most favourable circumstances; but in a country like this, where we suffer so much from dull weather, and may be without sunshine for a week or two, the possession of an especially sensitive film is, at times, very useful. No doubt the gelatine film requires a little different treatment to wet plates, and some additional precautions are necessary, such as the shading from light during the operation of sensitizing, and care in preventing the deposition of dust during development. Any dust particles floating about and attaching themselves to the gelatine film are certain to bring about spots and blemishes of a pronounced character, for particles once adhering are not to be removed. But this difficulty is readily overcome by many workers by keeping the plate during development submerged in solution, when, of course, it is quite impossible for any dust to become deposited. Unfortunately, many operators do not like this plan of working, being so accustomed to have the plate immediately under their eyes, and this cannot well be done unless the negative is held in the hand. At the same time, if the gelatine plate is to become of regular use inside the studio, and to take the place of the wet collodion film, as many believe will be the case, the operations involved in its manipulation will soon grow familiar to the ordinary worker. Certainly

its qualities, which render it so suitable for dull weather operations, cannot be passed over in a country like ours.

Painters and Photographers, and their Treatment by the Copyright Commissioners.—Photography was a good deal talked about at the copyright meeting the other day, held under the presidency of Sir Coutts Lindsay. The gathering took place at the Grosvenor Gallery, and may, therefore, be regarded an action altogether independent of the Royal Academy. Besides the chairman, Mr. Fripp, one of our foremost water-colour painters, Mr. Albert Moore, and Mr. Herkomer, the Paris gold medallist, took a prominent part in the proceedings. One of the questions involved was how far copyright in a painted portrait should extend. It seemed the general opinion of the meeting that the copyright of a painting should always remain with the producer, no matter whether he sold the original or no. To part with his painting should not mean that an artist parted with his copyright too. But there were to be exceptions to this rule, and one was in connection with portraits. In this case, it was held that the same rule should hold good as that framed for photographic portraits, Mr. Fripp moving "That the suggestion of the Royal Commissioners in relation to photographic portraits on commission should apply to all portraiture, and that the author of a portrait executed on commission should have no power to do anything in the exercise of his copyright without the sanction of the person who ordered it." Sir Coutts Lindsay justified this mode of looking at the matter in his speech in alluding to the difficulties which the commissioners meet with in defining copyright in portraiture. "They seem," he said, "to have been much puzzled to define what a portrait was, so as to class it in a different category to art compositions. It appears to me that the reason why the copyright in portraiture should remain with the commissioner of the picture is very simple. A man has a right to his own identity, either in a picture or otherwise, and it would certainly be unjust and unfair to publish the features of a man who wished to remain private." Then Sir Coutts Lindsay went on to show how the commissioners proposed a different rule for the photographer and the painter. The law which relates to painting the commissioners "propose to apply to drawings, lithographs, and to all other productions of the artist's pencil; but the laws they propose to apply to photographs are very different. They propose that the copyright in photographs should belong to the producers, except in the case of portraits, when it should belong to the commissioner who orders the portrait. "But there must be the same difficulty," continued Sir Coutts Lindsay, "in defining a portrait in photography as in painting, and I do not see how they can establish one set of rules for one art and a different set for another art." The argument of the commissioners, no doubt, in recommending that the copyright of a picture should be sold with the picture itself, was that they looked upon a painting and its copyright as indivisible, whereas in the case of photography it is not the original image (the negative) that is sold, but a copy of it. At the same time the reproduction of paintings, it must be remembered, is growing every day more and more frequent, and where previously but one was reproduced, twenty are copied to-day in one way or another. The consequence is there is a demand for copyright. A picture is purchased now-a-days as much for copyright as possession. And, as a rule, he who desires the copyright does not care for the original painting: the latter becomes the property of some nobleman or gentleman for his gallery, while the copyright is purchased by an art-publisher. Hence the separation of copyright and picture has of late become a matter of importance both to artists and to buyers of pictures. And as there is a tendency more than ever now-a-days to multiply paintings by engraving, etching, or photography, painters are especially awake to the value of their copyrights. Another reason may also be assigned, and that is that the painter, if the

copyright is separate from his work, is able to exercise some control over the mode of reproduction. He can prevent, for instance, the picture being reproduced in a publication or form of which he does not approve, and this is a point of some consideration; whereas if you part with everything when you sell your picture, you can do little in this respect. One other point which will strike photographers in reading the report of the meeting is the kindly manner in which the president, Sir Coutts Lindsay, speaks of photographic art and acknowledges its value.

GERMAN CORRESPONDENCE.

AWARDS OF THE INTERNATIONAL EXHIBITION OF PARIS, 1878
—NEW RAPID PROCESSES—NEW PHOTOGRAPHIC APPARATUS—TENT CAMERA—PROGRESS IN PHOTOGRAPHIC LENSES—DEATH OF DR. E. STEINHEIL.

BY DR. VOGEL.

DR. VOGEL writes to our Philadelphia contemporary, and says:—

The Exhibition is closed, and the list of awards was finally published about a fortnight before. Notwithstanding the immense quantity of awards, the general sentiment is an unsatisfactory one (of two hundred French exhibitors, one hundred and seventy obtained an award of merit, as also every one of thirty-three Austrian exhibitors). The disappointment has its reasons. Mr. Levitzky, vice-president of the photographic jury, relates that still in the month of October decisions were made by a non-authorized jury, changing the decisions of the regular jury. Three more gold medals were awarded, and one of them by special influence of the Grand Duke Constantine of Russia.

Mr. Seavey, the first background painter of the world, is not among the fortunate. He had to be contented with a bronze medal, although his work and qualities justified the expectations of the highest reward.

After the excitement caused by the Exhibition, the rapid processes are the principal subject of attention. First of all was the lightning process of Boissonas and Klary, which has proved to be a failure; then came M. Richard, whose process has carefully been tried in Berlin, with his own chemicals, and found to be not a particle more sensitive than my own chemicals. There are also Mr. Sehweg and Mr. Fricke. All these processes are kept secret, and are offered for sale.

At a meeting of the Society for the Advancement of Photography, M. Ball has described a method with which he thinks to reduce the exposure one-half. He connects two silver corners of the plate-holder with the two ends of a galvanic element, so that a stream goes in the diagonal direction of the plate. He has shown proof plates, one-half of which was exposed in the usual manner forty seconds, and the other half only twenty seconds, by the application of a galvanic stream, which spoke well for the usefulness of his method. I have tried it, but not with entire satisfaction, which may, however, be due to the insufficiency of my stream. His ideas are certainly worth a trial.* We had, therefore, in all five rapid processes, and the search for the same is still so decided, that it is not at all astonishing that one of our members asked, at the end of the meeting, if, during the same, "no other new processes were invented."

The principal object of this investigation is the abridgment of exposure. Parallel with it go the experiments with gelatine emulsion. The gelatine emulsion plates by Bennett and Kennett are exceedingly sensitive, and surpass the wet-plate in regard to rapidity. At present photographers are not in favour of this proceeding, as the preparation of gelatine emulsion plates is a very

inconvenient thing. However, they have the advantage of allowing preparation beforehand, and keep their sensitiveness for a long time. It would be possible to manufacture the plates on a large scale and put them in the market, which would save to photographers the inconvenience of preparing the plates. The general use of a process is not only dependent on the rapidity with which it allows to work, but principally on the quality of the work turned out; and I must say, in regard to this, that the proportions in shading are inferior to those of wet plates.

Four new photographic patents have recently been granted, as a proof of our assiduousness. There is one for a method of making enlargements on linen, one for a portable photographic outfit, one for photographic transfer paper, and finally one for transferring. Two applications for other patents have been made, one a hot burnishing machine, and one for a photo-chemical printing process. That everything is not new does not need to be mentioned. The portable outfit, for instance, resembles much a construction known under the name of "tent camera." Especially fresh to my mind is a construction which Davis exhibited in London in 1862. The improvement of the apparatus is the combination of tent and camera, which seems to be very practical and compendious as long as you look at it; however, as soon as you are going to work, the thing changes its appearance. In landscaping, for instance, where there is the camera to be transported, lowered, and inclined in all directions, it will be a very inconvenient thing to move all the bottles and dishes with it. It is a very unhandy whole, which does not promise much of a future.

Another process, not patented yet, is an improvement on portrait lenses, operated by Voightlander. In consideration of the progress optics has made during the last thirty years, it is astonishing how much the portrait lens has kept its old form, originally introduced by Petzval. The sole change ever made on it has been operated by Dallmeyer, who simply turned the back lens and added a construction by means of which the two lenses which compose the back lens may be put into different positions. He thus hopes to obtain the depth of the focus. The efforts made in Germany for the improvement of the Petzval lens were equally visible. A fault with the same is, that the two back lenses have to be separated, and are thus the cause of many optical faults, loss of light by reflection, &c., caused by a disadvantageous position of the same. I have worked with lenses which gave a bad picture, especially with regard to sharpness of outlines; I improved them by changing the thickness of the paper put between the two lenses in question, and found thus in an experimental way what distance was the best. Several opticians have tried to introduce lenses in which the two back lenses were cemented together. Busch exhibited one of these in Vienna in 1873. It worked very nice, but has never been put in the market. Steinheil made similar trials. Voightlander has sent me recently a portrait lens with a two and three-quarter opening; it was a portrait lens of an old construction, for carte-de-visite and cabinet size, of ten-inch focus. At the same time he sent me a back lens, with the prescription to replace with it the back lens of the objective in operation. The effect was wonderful. The focus was reduced to seven and a-half inches, and the light on the plate proportionately strengthened. I found that a plate required twenty seconds' exposure with the new lens, whilst the old ones required thirty-five. Sharpness and depth of focus were satisfactory.* Whoever possesses a Voightlander lens need only to buy a new back lens, in order to shorten the focus considerably. This may be of some value to practical photographers. The new back lens is composed of two lenses cemented together, and nearly symmetric to the front lens; the consequence

* The use of a galvanic current during exposure is a very old idea in photography, having been tried in Daguerreotype days with the sensitive silver plate. It was not found, however, of practical value.—ED. PHOTO. NEWS.

* Mr. Dallmeyer made a similar experiment some years ago, but found that the shorter focal length required by the front, as compared with the back combination, to cure barrel-shaped distortion, introduced so much astigmatism that it had to be abandoned.—ED. PHOTO. NEWS.

will be that the new instrument will give much more correct drawings than the old one. It is still a question if this improvement is applicable for larger instruments, as I tried until now only a small size. Another lens recently tried by me, which is not manufactured for the trade, is especially designed for the reproduction of drawings, and for the taking of landscapes. It has a peculiar construction. It is composed of two systems of lenses two inches apart, each one of which is composed of two lenses. The component parts of every system are a nearly plano-convex crown-glass lens, which has four and a-half inch radius on the convex side, and a nearly plano-convex flint glass lens of six-inch radius on the convex side; both lenses are not cemented together. The concave side of the flint glass lens is facing the nearly plane side of the crown-glass lens. I obtained some very good results with it, which prove that in the line of lenses still more important improvements are possible.

We have to regret the death of another celebrity of photographic art. Dr. E. Steinheil, member of the firm of E. and A. Steinheil, of Munich, died on the 11th of October, on board of the steamer *Silesia*, on his way to St. Thomas. He died of apoplexy, though the journals called him a victim of the yellow fever. He intended to go to South America for the sake of his health, and in order to apply himself to the study of butterflies (an old passion of his). Dr. Steinheil had made this trip several times. He is buried in the churchyard of St. Thomas. The optical institute is carried on by A. Steinheil, brother of the late E. Steinheil.

TO MAKE VIGNETTERS BY MEANS OF GELATINO-CHROMATE.

BY DR. J. SCHNAUSS.*

THERE are so many different kinds of vignettors now offered for sale by dealers, that I was induced to try and prepare some for my own use, and by following the method I succeeded in obtaining what I required. From a good positive in black or some non-actinic colour a number of negatives of different sizes are taken, but in doing this the image on the ground glass plate must not be focussed too sharply. Or where suitable vignettes are already at hand, the negatives can be taken from them directly by any convenient method; either a collodion emulsion may be used, or chromated gelatine as described below. To prepare the latter a solution is made of five parts pure white gelatine in sixty parts of water, to which two parts of ammonium bichromate are added; and, when the film is afterwards to be drawn off, a few drops of glycerine may be introduced to make it less brittle. After filtering this solution, pour it, whilst still hot and fluid, on a well cleaned glass plate; care must be taken to have this plate placed in a perfectly horizontal position, which is best effected by resting it on a larger plate that has already been carefully levelled. The gelatine solution must not be allowed to run over the sides of the plate, or the film may turn out to be too thin; to prevent this give the plate a raised edging of wax. When the chromated gelatine has set, let the plate dry completely in a dark and moderately warm room. Artificial heat should not be used in drying, especially when the film is afterwards to be drawn off; when this is the case the plate should first be rubbed over with powdered talc or diluted ox-gall, and then on heating the film easily flies off.

On plates prepared in this way the negatives are now copied, and that as intensely as possible by a long exposure. The copies cannot be too intense, provided that the negatives are quite black in the centre of the aperture. When they have been sufficiently exposed, wash them several times in cold water, and finally with distilled water; then plunge them, while still wet, into a solution

of one part lunar caustic in fourteen parts water acidulated with one part acetic acid.

It will now be seen that the film is coated with a precipitate of silver chromate, which is in the highest degree non-actinic, and is much denser towards the sides of the plate. Should there be a trace of chromium salt left, as is often the case, it is of no importance; on the contrary, when really intense vignettors are required, it is not necessary to thoroughly wash out the chromium salt. But in order to obtain the requisite transparency in the centre of the plate, the whole of the silver nitrate must first be washed out, and then a soft and strong hair-brush dipped in dilute nitric acid: this is passed over the plate with a few rapid strokes in a circular direction from the centre outwards up to the commencement of the shading, and the plate is then quickly rinsed. With a little skill a great variety of effects may be obtained in this way, and any required degree of shading.

After drying, the film is coated with a little castor oil collodion, and then, if it be desired to draw it off, with a hot twenty per cent. solution of gelatine to which a small quantity of glycerine has been added. The plate must be laid horizontal, and the addition of a little alcohol to the solution facilitates its flowing. When the gelatine is set, the plate is placed for a couple of days to dry, and it is again coated with some thin collodion; the edges are then cut through, and the film is drawn off.

COPYRIGHT IN WORKS OF FINE ART.

A MEETING was held on Saturday last, in the Grosvenor Gallery, to consider the contemplated legislation in relation to the copyright in works of fine art. The following report is condensed from the *Times*, which also devotes a leader to the subject:—

Sir Coutts Lindsay, by whom the meeting had been invited, was called to the chair, and proceeded to explain its purpose. He understood that the Government intended immediate legislation on the subject. At present the law was very anomalous, and its effect was to give neither the purchaser nor the producer of a picture any claim to the copyright except by special contract and in the case of works done on commission. He went on to say,—That such a state of things should exist seems to me to be unworthy of the legislation of England, and it is high time some more complete form of law should be promulgated. I find among the Commissioners—first, the president who represents the Government; several lawyers; two literary men, Mr. Froude, and Mr. Trollope; a scientific gentleman; a musician, Sir J. Benedict; but there is not a man having any interest in art. No representative of the interests of art was nominated on the commission—a most unfortunate circumstance, and one which, probably, has affected the resolutions of the commission very injuriously in the interests of art. The laws respecting painting, drawing, photographs, and sculpture have been framed at different times, and, therefore, there is little or no uniformity in them. There is great disparity in regard to copyright in them, both as to the time they enjoy protection and also in other divisions of the matter. Hitherto artists have enjoyed copyright during life and seven years after death. With regard to sculpture, it has been fourteen years after production and fourteen years after if the sculptor is then alive. By the present law an artist sells a picture without having the copyright reserved to him, he loses possession of it, while the right does not vest in the purchaser unless there is a written agreement to that effect. This copyright becomes the property of anybody who wishes to make use of the idea which ought to belong to the artist. If a painting or art work is done on commission, then the work belongs to the commission, and ceases to be the property of the artist. There is no doubt fresh legislation is needed on that point. Such an anomaly has never before existed in English law, and I think I express the feeling of the meeting in saying we are grateful to the Government for proposing to legislate. But it behoves us and the societies to watch over our own interests, and it is for that purpose alone that this meeting will be of utility to art. We are bound to watch the action of the Government, not in an inimical spirit, but to give such advice as we think we are capable

* *Photographisches Archiv.*

of giving to direct legislation in the interests of which the commissioners have taken some pains to ascertain what are the feelings of artists by examining different artists. The commissioners state that one of their chief difficulties was the proper right of copyright in portraiture. They seem to have been much puzzled to define what a portrait was, so as to class it in a different category to art compositions, and asked many questions not tending to elucidate the matter. It appears to me that the reason why the copyright in portraiture should remain with the commissioner of the picture is very simple. A man has a right to his own identity, either in a picture or otherwise, and it would be certainly unjust and unfair to publish the features of a man who wished to remain private. It is the identity of the man which ought to be protected, and not the picture, and that seems to me to be the simple rule which the Legislature must follow in legislating with respect to portraiture. The law which relates to printing they propose to apply to drawings, lithographs, and all other productions of the artist's pencil; but the laws they propose to apply to photographs are very different. They propose that the copyright in photographs should belong to the producers, except in the case of portraits, when it should belong to the commissioner who orders the portrait. But there must be the same difficulty in defining a portrait in photography as a painting, and I do not see how they can establish one set of rules for one art and a different set for another art, especially as I give that difficulty as one of the chief reasons why they legislate upon art to the disadvantage of the artist. Another objection to the proposed legislation is that they insist upon compulsory registration of all works of art when sold. Such a proposal seems to me to be absolutely preposterous. Artists produce important works where registration is perfectly advisable, but they also produce what are vulgarly called "pot-boilers," whose registration would not only be a heavy tax on the artist, but a most unbearable burden in other respects, and I think the proposal would be quite unworkable. I do not think I have said that the Commissioners propose to make the enjoyment of copyright co-equal in literature, art, and the drama, viz., during life and for thirty years after death. We cannot be too grateful on this point for the proposal of the Commissioners. In dealing with copyright as affecting the purchaser and producer, had the Commissioners included some artist or some professional man who understood the whole rights of the case, I do not think they would ever have made there unfortunate proposal, for it would be understood that there are two properties in a work of art—one consisting of the picture, and the other of the idea. When a painter parts with a picture he parts with a valuable production; but if he is forced at the same time to part with the idea, he parts with that which may be of infinitely more value to him than the canvas he has worked upon, for it is something which must be, and often is, useful to him for the rest of his life. It appears to me a most cruel form of legislation to make a man part with two different properties in one sale. It is contended by the Commissioners that any artist may contract himself out of the legal arrangement which they propose, and no doubt that is the case; but that does not alter the general course of law, nor does it alter the general disposition of the purchase and sale of that property. There are two classes of purchasers of art productions; one purchases a work for his own peculiar pleasure and benefit—he may be called the amateur, if you please—and the other is the dealer, who purchases for the profit of re-sale. The amateurs form the largest and most important class, and a class much more to be encouraged than the other. If the Commissioners proposal became law the amateur class would become possessed not only of pictures, but of the interests of artists in them, and in the case of piracy of such pictures the artist would be unable to protect himself or his work, as the duty of protection would devolve on the purchaser. In this case it appears to me that the artist would get no sort of protection whatever; for if he claimed protection against piracy or photography, not one in a hundred of the *dilettanti* purchasers of works of art would take the trouble to protect him. The dealers, I take it, are very well able to protect themselves, and I do not understand why the Government should be so anxious to put them on a bed of roses, when they are so well able to put the artists on a bed of thorns. The Commissioners, in forcing on the artist the registration, would impose a very onerous duty; whereas, if the copyright was vested, as it should be, in him, the necessity for registration would immediately drop. A resolution, therefore, will be submitted to you to that effect. Another important point which the Commissioners do not seem to have seen is the

question of *replicas*. It is a subject of some delicacy, and, as an artist myself, I would insist that all artists should have the right to reproduce the ideas which they have embodied on canvas, but that identical *replicas* should not be allowed, for the simple reason that a reproduction which is identical must damage the identity of the first work, and, in doing so, diminish its value. But that an artist should be deprived of the power of using his finest ideas because he has already embodied them seems to be preposterous, and cannot but be most hampering and injurious to the interests of art, not only of the present day, but of a thousand years hence.

Mr. FIELD then recounted the history of artistic copyright legislation from Hogarth's time to the present day, and remarked that painters only asked that they should not be placed in a worse position than a mechanic with a box of chemicals.

Mr. RICHMOND then moved:—"That, while welcoming the report of the Royal Commission as exposing the grave defects of the existing law of artistic copyright, and recognizing the value of many of its recommendations, this meeting is nevertheless of opinion that, in regard to its main provisions, the interests of the public could be as adequately secured by means less injurious to the interests of art."

Mr. ALBERT MOORE seconded the proposition, and it was carried unanimously.

Mr. A. D. FRIPP, seconded by Mr. KEELEY HALSEWELL, moved a resolution to the effect that, except in the case of portraits and *replicas*, the right of reproduction should remain with the painter, unless he specifically parted with it.

Mr. A. LUCAS, seconded by Mr. SADLER, moved an amendment in favour of the recommendations of the Commission.

The amendment was lost, and the original resolution was then carried all but unanimously.

Mr. HERKOMER proposed the third resolution:—"That while admitting the value of registration as applied to forms of art like photography and engraving, which are susceptible of exact and perfect mechanical reproduction, we are nevertheless of opinion that it would prove a vexatious and ineffective mode of protection for the design in works of imaginative art, of which the value depends upon the handiwork of the artist himself in the expression or embodiment of such design, and which are, therefore, incapable of precise verification by means of description or copy."

Mr. LEIGHTON seconded the resolution, which was carried, there being only one dissentient.

Messrs. Fripp, Richmond, A. Moore, and Herkomer were nominated as a deputation to bring the resolutions of the meeting to the notice of the Government, and the proceedings ended with a vote of thanks to the chairman.

In a letter to the *Times*, after the meeting, Mr. Arthur Lucas, upholding the view of the commissioners in opposition to that of the painters, says:—

What the Royal Commissioners have sought to do is, not to deprive painters of their copyright, but to express clearly that this untenable distinction between conception and embodiment shall not exist, and that copyright shall attach—where it is only logical to seek it—in the embodiment or picture, and that without it be expressly reserved it shall belong to the purchaser and follow the ownership of the painting.

It cannot be too emphatically stated that the interests of painters and the body which I represented at the meeting of Saturday last, the art publishers, are absolutely identical. We, the publishers, distinctly desire that artists should derive every possible benefit from the eouage of their brains, and we wish to see the laws defining their rights clearly expressed in our statutes. There are, however, two distinct kinds of copyright—firstly, the right to reproduce by engraving, or some of the more mechanical processes, which applies only to a very small percentage of pictures; and secondly, the right of an artist to repeat, or make replicas of his own works, which applies, of course, to every picture. It is this second right which so many artists are so loth to use, and here it is that their difference with the recommendations of the Royal Commissioners is most accentuated.

My own personal view is that the strict morality of a replicas is at least extremely doubtful; many of our best painters utterly condemn it. It at least shows a poverty of conception, and is defensible only where the purchasers, both of its original work and its repetition, are each made cognizant of the existence of the two or more works.

FINE ART COPYRIGHT.*

THE artists who assembled in the Grosvenor Gallery on Saturday night were very much of one mind, but they have failed to convince us that the balance of argument is not strongly against the propositions they met to advocate. The question most seriously agitated by them turns on the right of reproducing pictures. A painter paints a picture and sells it to another man. The artist and the purchaser may make any agreement they please between themselves touching the subsidiary rights connected with the picture. The picture itself belongs, of course, to the purchaser; but the artist may stipulate that he shall retain the right of making and selling copies of it, whether on a reduced scale and in a different medium, or as exact *replicas* of the original production. The artist may stipulate, again, that he shall have the right to authorize engravings, etchings, lithographs, photographs, or other forms of translation; and if there are any rights relating to a picture other than that of its direct possession and enjoyment, the artist may reserve them to himself. On the other hand, the agreement between the two may be that the purchaser who acquires the picture by his purchase shall simultaneously acquire all rights connected with it such as we have described. The law allows the utmost freedom of contract between the two, and there is no intention on the part of any one to interfere with this freedom. The Copyright Commission never made any suggestion to limit it. What, then, is the question that agitates the artists? It is this:—Suppose a picture bought and sold and nothing said about copyright, whose shall the copyright be? In the absence of express agreement, in whom shall the copyright be vested? The law is now in that absurd condition that in the case supposed the copyright belongs to neither the one nor the other; it may be said to be in the air, for it can be asserted against nobody; but there are very few, if any, who think that the law should remain in this state. Where, then, shall the rights to which we have referred be vested? The Copyright Commission recommend that they should go with the picture and belong to the buyer, unless the seller expressly contracts that they shall be reserved to him. The artists at the Grosvenor Gallery are all of opinion that they should remain in the seller, unless the contract expressly includes them in the purchase. They make, indeed, two exceptions to this principle. They think, and it is very good of them to think it, that if a man gives an artist a commission to paint his portrait, the painter ought not to be allowed to reproduce it, or to have it engraved, lithographed, or photographed, except with the permission of the man himself. Also they think that the right of a painter to make *replicas* of a picture he has sold should not entitle him to reproduce it so perfectly "as to imperil the identity of the original work." Subject to these two limitations, they hold that an artist selling a picture must be understood to retain all rights of reproduction, unless it is expressly agreed that they go with the painting.

There is a preliminary question whether the law should recognize and protect such rights of reproduction of a picture as we have described. We look with great jealousy on all proposals to extend the law of copyright; but it must be admitted that these privileges of reproduction and translation are capable of being made subjects of contract, and are, in fact, often transferred for valuable pecuniary considerations. Consequently, the sanction of the law can hardly be withheld from what thus acquires, by the agreement of men among themselves, all the attributes of property. Sir James Stephen, who was one of the Copyright Commission, disapproved of copyright in pictures, "because a picture has a value of its own which is not affected by its being copied, and copies of it are themselves works of art of various degrees of merit;" but a picture may have two or three springs of value, and the recognition of one is no valid reason for refusing recognition of another. Sir James Stephen, somewhat strangely, does approve of copyright in engravings, although the foundation of a copyright in an engraving is the copyright in the picture from which it is engraved. These questions must be settled by facts. Mr. Millais paints "The Order for Release." If he can convey to a publisher the exclusive right of engraving it for a limited number of years, that right would sell for a considerable sum. If he can retain the right of copying it, the right would be worth a considerable sum. As these rights can be defined and

appraised, there seems no adequate reason why the one, like the other, should not be recognised by the law. We may assume they will be recognized, and will return to the question whether they should be vested in the purchaser or remain with the artist in the absence of an agreement. Many may be disposed to ask whether the point is of any importance, since it can be settled by agreement. The eager interest of artists in it shows that it is of some importance. The fact is, they think that if the question is once mooted between an artist and a purchaser, the latter will insist upon retaining all rights the law gives him, but if there was no necessity to mention it, the purchaser would rarely be alive to it. The Copyright Commissioners said "the evidence shows that persons buying pictures do not in general think about the copyright, but if the subject happens to be mentioned they are generally under the impression that the copyright is included in the purchase, and are astonished if they are told it is not." The artist knows all about the point; the purchaser does not; and if the law gave the artist, in the absence of agreement, all rights of reproduction, the purchaser would not get all that he thought he was buying. If the rule of law is the other way, the artist will never lose a right without knowing it; if the rule is as the Grosvenor Gallery meeting desires, the purchaser will constantly fail to acquire rights he thinks he is purchasing. This of itself appears to us conclusive in favour of the recommendation of the Copyright Commission. Throwing upon the artist the burden of stipulating for what he wants gives him the opportunity of obtaining every power he desires without injustice to any one. Other arguments founded on convenience may be suggested. It is plainly not very convenient that the right of possession of a picture should be in one person, and the right of multiplying copies of it in another. This separation of rights may be created by agreement, but we want some positive argument of considerable cogency to support the suggestion that the law should separate them on every sale. The exceptions the artist themselves have been constrained to make in their own principle afford further arguments against its adoption. They are obliged to allow that a man who paints a portrait on commission should have no rights of reproducing it, except by express authority; and why should a man who paints a scene in a park on commission from its owner have the right of reproducing it? Again, they say that a *replica* should not be permitted "to imperil the identity of the original work;" but this rule would still throw upon the possessor of the original work the necessity of taking action, and of proving that the *replica* exceeded allowable limits of reproduction. Under the contrary rule, whereby the artist could not reproduce what he had sold except by authority, he must apply for authority; he must satisfy the possessor he is not going to confuse the value of his property—in a word, he must vindicate the innocence of his action. On every ground the proposition of the Copyright Commission commands our preference.

The artists in the Grosvenor Gallery had a great deal to say about the proposal of the Copyright Commission on the subject of registration. They did not question "the value of registration as applied to forms of art like photography and engraving," but they denounced it when applied to pictures. What do the Commissioners recommend in this matter? They say that as long as the property in a picture and its copyright are vested in the same person no registration whatever is necessary, but when these are separated there should be compulsory registration of the agreement by which copyright is separated from possession, coupled with a brief description of the nature and subject of the work the subject of the contract. Registration, therefore, would never be required, except when one man owns the picture and another has the right of multiplying copies of it. It is then recommended simply for the purpose of proving the right of the person entitled to make copies; and as this is done for his convenience, its compulsory character might be dropped if he objects to it. This would, however, be no boon to the artists. If they got their own way and the privilege of copyright was reserved to them in the absence of agreement, they would be obliged, if they wished to prevent any person interfering with their rights, to establish that precise verification of their work which they resolved on Saturday was difficult to the verge of impossibility. Registration would help them to do this: but if they would rather postpone all proof of title till a question arose in a court of law there is no reason why they might not be permitted to have their desire. All this is, however, subsidiary to the main question that agitates them, and we have intimated with sufficient clearness how we think that must be decided.

COPYRIGHT IN PICTURES.

WE print on another page an interesting report of a meeting called to consider the contemplated amendment in the law of copyright in works of fine art; we also print a leader which was devoted to the subject in the *Times*. The subject cannot fail to interest photographers, both in its relation to paintings and to the productions of their own special art. That the existing Act on the subject is unsatisfactory in many points cannot be denied. It is not only clumsy, complicated, and obscure in many respects, but it is also unsatisfactory in some of its enactments. As the law at present stands, unless written agreement is entered into defining the ownership of the copyright, no property in the idea or design of the picture accrues to anyone. The artist loses that property, whilst the purchaser of the picture does not acquire it; and neither would have a remedy against anyone else making unauthorized copies. The recommendation of the Royal Commission appointed to consider the subject is that the copyright in a painting shall pass with the sale of the picture to the purchaser, unless a written contract to the contrary be entered into at the time of sale. To this provision the artists very naturally object, as they consider that the design or idea of a picture having a distinct value of a negociable kind apart from its first embodiment on the canvas or other material, should vest in the creator of that design in the absence of any definite sale thereof. The copyright of a picture, embodying the right to multiply it by engraving, photography, or other means, is often the most valuable part of the property, and as it should vest in some one apart from any agreement, naturally, we think, vests in the author.

Curiously enough, and satisfactorily also, the law to be applied to photographs is, as we understand Sir Coutts Lindsay, to be different to that proposed for paintings. It is proposed that the copyright in photographs shall belong to the producers, except in the case of portraits, and the copyright in portraits is to belong to the person for whom the portrait is produced. This, at first sight, seems to be legitimate enough. Most persons will assume that a man's copyright in his own portrait is beyond question. But there is an aspect of the subject in which this dictum is decidedly adverse to the portraitist. A portrait by an accomplished artist is not simply a mechanical facsimile of a face in which the owner of the face may be asserted to have an indefeasible copyright. It is something more: it is a work of art, in which all that is artistic belongs to the portraitist. If by producing this work of art he acquire no sort of right in the multiplication of it, if one copy produced and sold may, without hindrance or check, be produced by any mechanical workman in exact facsimile, the original artist is surely seriously injured. His thought

and skill as an artist cannot reasonably be remunerated by the sale of a single copy, and he ceases to be fairly paid for his work.

But this is not the only injury from which he suffers. We must here re-affirm a position we have often maintained as to the essentially artistic possibilities of photography. The true artist in photography will stamp his impress upon his art as decidedly as the painter. A connoisseur in photography will recognize at once by its style a Rejlander or a Robinson, an Adam-Salomon or a Blanchard; and let a portrait by a great master in photography be reproduced by a cheap mechanical copyist, the style and characteristics will remain. If, however, such copies are imperfectly reproduced, as they generally are, the style of the master will suggest identity with his work, and the fading and other imperfections of printing will attach as a stigma to his work. He will thus be not only robbed, but disgraced.

The remedy upon which the *Times* insist for painters will, it is true, be available here for the photographic portraitist. It is asked, how can the enactment of the statute affect the question when the ownership can be settled by agreement? The artist feels it will materially affect the question, and the portraitist will feel the same. If the question of ownership in the right of reproduction have to be raised, difficulties will occur which might be avoided. If the law give the copyright to the purchaser, he will often be disposed to show a degree of concern and tenacity as to retaining it, which he would not have felt if the law had not conferred it upon him. A thing once in possession often acquires a degree of importance in its possessor's eyes it does not possess in the abstract. The purchaser of a painting often buys the picture for the pleasure its possession will afford him, and never dreams of copyright; but if by the provision of the law copyright passes to him by the act of purchase, he will be ready to feel aggrieved if he is asked to sign an agreement by which the copyright remains in the hands of the painter. So in like manner with the smaller matter of the photographic portrait. As a rule, no thought of copyright enters the mind of the sitter: but it will acquire a sudden value in his eyes if explained to him, and he is asked by agreement to forgo it.

But it will be contended, not unnaturally, that it would be obviously unfair to leave in the hands of the portraitist the right to multiply and publish portraits of his sitters without their permission. Clearly so: and a provision limiting their right to use a portrait for any purpose without the permission of the sitter might with great propriety be inserted in the Act. Indeed, such a clause protecting the public, and furnishing a simple remedy, might be very desirable as deciding a question which has occasionally arisen as to the exhibition of portraits in defiance of the expressed wish of the sitter. But that the copyright shall as a matter of course pass to the sitter, or person ordering the portrait, appears to us to be at once unfair, inconvenient, and useless, injurious to the portraitist, and of no value or advantage to the public.

There is one specific advantage given to artists in the proposed amendment which is worth note. The Royal Commissioners propose that copyright in literature and art shall be extended, and be enjoyed during life, and for thirty years after death.

LIGHTNING PROCESSES.

OUR readers are probably aware that in America photographers or their organs get very much in earnest, and base furious wars on difference of opinion as to the excellence of a process. An amusing little episode arises in relation to what is termed the "Lightning process," in which our Philadelphia contemporary, an opponent of the "lightning process," gives unconscious testimony as to its excellence. Mr. Notman, of Montreal, has been recently

advertised as one of the converts to "lightning," and our Philadelphia contemporary explains this by suggesting that the Mr. Notman, Mr. William Notman, does not dabble with chemicals himself, but gets his people what they like. And amongst his people is one of his brothers, John, who is fond of novel experiments, and was once a discoverer of a rapid process himself. The writer quotes, in illustration of this, a communication to *Snelling's Photographic and Fine Art Journal* of twenty years ago. A glance at the formula is very interesting. It is just about twenty years ago, as old photographers will remember, that a war waged fiercely as to the use of iron development for negatives in place of the old pyro system. Pyro was dethroned and iron reigned, an enormous reduction in exposure being gained by the change. Mr. Notman was one of those who early and definitely adopted the new and improved method. Instead of suggesting, therefore, that Mr. John Notman is easily led away by novelties, the natural conclusion is that he is quick to recognize improvements, and that if the lightning process of to-day be as great an improvement as was iron development twenty years ago, it is well worthy of consideration. We do not enter into the controversy, but would like to hope that the claimed rapidity is found a reality by those who test it. It is amazing to remember the bitter tenacity with which old pyro was retained and defended as the best developer twenty years ago.

EXTENSIVE AND SUCCESSFUL PHOTOGRAPHIC ENTERPRISE.

We find in one of the metropolitan district papers, the *South London Chronicle*, an interesting sketch of successful photographic enterprise, narrating something of the career of Messrs. A. and G. Taylor, of Forest Hill, Queen Victoria Street, and we know not how many more places. We are told, by the local journal in question, that "the career of the gentlemen merits a chapter in a future edition of 'The Romance of Trade,' and is another illustration of the truth that intelligent perseverance and clear-sighted enterprise will always command their reward. Established in comparative obscurity, a few years ago, when its whole staff could be enumerated on the fingers of one hand, this firm at the present time claims, and claims justly, to be the largest photographers in the world. By untiring industry, strict integrity, and great skill in their profession, Messrs. Taylor have won for themselves this proud position. With their headquarters in London, they have established branches in all the great centres of commerce in the United Kingdom. On the Thames, the Mersey, the Clyde, and the Liffey, they are equally well-known. They have a studio in the most fashionable of the Paris Boulevards, and now, having conquered the Old Continent, they have sent out an expedition to win the New. In the course of the next few weeks, studios will be established in New York, Boston, Philadelphia and Chicago."

It will interest many photographers to learn that the managing partner to the firm, who has gone out to conduct this American enterprise, is Mr. J. Traill Taylor, late editor of the "British Journal of Photography," and the following interesting particulars of his recent departure are given. Our local contemporary says:—

"We may mention, in passing, that this gentleman was entertained at a farewell dinner just previous to his leaving England, and presented with a testimonial valued at 200 guineas. He is possessed of great literary ability, and contributions from his pen have occasionally appeared in the *Journal of the Society of Arts*. We have no doubt he will bring to bear upon his new duties that energy and force of character for which he is so distinguished. Saturday, the 11th of January, was the date fixed for the departure of the good ship *California*, of the Anchor Line, and the Victoria Docks the scene thereof, and many

were the preparations for the memorable event. In addition to the gentleman above mentioned, the emigrating party consisted of fourteen operators and men skilled in the enlarging process, besides colourists, for all of whom first-class berths had been provided. As the hour approached for the departure of the vessel, the last adieux were exchanged with the immediate relatives, and the deck left to the members of the firm, who had come to see their comrades off, among them being Mr. George Taylor, their respected principal. A rather amusing incident occurred just at this juncture. As the friends were about leaving, the vessel moved from the dock sooner than was expected, and prevented the possibility of landing, and there was no help for it but for the visitors to accompany the vessel to Gravesend, and there reach terra firma. We cannot speak too highly of the admirable arrangements made on board for the comfort of the passengers, or the generous hospitality shown to those friends who accompanied them down the river. Luncheon was served in first-class style, and previous to parting the whole party joined hands and expressed their feelings in singing 'Auld Lang Syne.' The last farewell was exchanged, the last shake of the hand given, and as the tug moved off to the shore, the air resounded with cheers for the success of the American business, which were answered from the deck with cheers for Mr. George Taylor. We wish the project success, and the *California* a pleasant voyage.

We are further informed that "it is the intention of Messrs. A. and G. Taylor to establish, in addition to the studios above-named, a factory or depot on a very extensive scale, fitted up with every appliance that ingenuity can devise, for the production of their noted enlargements, and for the efficient working of the various mechanical processes in connection with photography. From this great central depot at Brooklyn will be issued those charming Excelsior portraits which, in the old country, are scattered broadcast, giving universal satisfaction, and which in the New World will carry on their mission, enabling the smart speculator of Wall Street, the not less smart New Englander, the rail splitter of the Western States, and for aught we know the 'tearless Stoick of the Woods' in his native wigwam, to secure the shadows of their friends ere the substances fade. The sending out of this photographic expedition is extremely novel in its character and original in its conception, nothing of the kind having been before attempted in the history of photography."

AN EARLY ARTISTIC PORTRAITIST.

A CORRESPONDENT of the *St. Louis Practical Photographer* gives an interesting reminiscence of a visit to M. A. Lam-Salomon's studio in 1862. After some preliminary remarks, he says:—

"At that time No. 58, Rue Laroche Foucauld, was the address of the man who had among his negatives the greatest personages of the day, and almost from every part of the globe. Let it not be supposed it was a useless precaution to have ascertained the exact number, because the street I have named is not a big or a fashionable one on some boulevard: it is narrow, unimportant, very quiet, just the sort of spot a man of moderate means, who loves study and peace, would select for his abode. On the small green door of a private house there was only to be seen "No. 58," not even a brass plate with name. The front portion of the establishment, including the door, was composed of a double sort of work-place; the first or ground floor was a sculptor's atelier, and above this a glass house had been arranged by knocking down some brick work. A small garden intervened between this and the dwelling house. There was nothing to be seen here of the present day arrangements, got up at immense outlay, and still greater cost of rent and taxes. This very modest and even mean-looking house, with its double work-shop, was

nevertheless the residence and place of labour of a true and great artist; one who has honoured photography doubly, in so much that he, being a clever sculptor, has abandoned the chisel for the camera, to become a still cleverer photographer. I must confess that my first impression was one of some disappointment, but it was soon dispelled by a very courteous reception. At a guess, Salomon was a man probably a little over forty, of the middle height, and it was very evident fully absorbed in the concerns of his work; so much so, indeed, that his good wife had to hunt him up and use her utmost powers of persuasion to make him partake of sufficient food to avert collapse. He would go a whole day without nourishment, she said, if she were not always after him. A great enthusiast, a hard worker, and a jolly good fellow for all that.

"Notwithstanding the prevailing fashion, a great demand for small photographs, it may be surprising to learn that Salomon never took one. He had but one size, one style, one price—the 8 by 10 size plate, half-figure, nearly always standing, plain background, and at \$20 first copy.

"No sitter was ever allowed to get out of his hands under anything less than two hours, and in that time from six to eight negatives were generally made.

"It is probably needless to do more than observe, cursorily, what an amount of study and care each sitter was made the object of. But he knew full well what he was doing, and it remained a question with me, from all I heard him say, whether he ever considered he had done his work well enough to satisfy himself. No one could print his portraits to his satisfaction. He observed: 'Those I am very anxious about I must do myself.'

"It may be asked how it came to pass that this photographer could resist the universal current (refuse to do the work in demand), and otherwise go counter to every established system of business? For all that, he had as much work to do as he could conveniently get through, in his own style and at his own price, and we may remain satisfied with the explanation that his superior talent did it. It is very evident that Adam-Salomou's true artistic method of leisurely proceeding had the desired effect, as evidenced by the very superior portraits he produced. His superiority asserted itself without any artificial aid, and brought to his door the greatest people it has ever been the good fortune of any photographer to greet within his walls.

"In point of business results, it will not be doubted that the results were just as satisfactory, when it is remembered that his daily average receipts amounted to \$200. All this work was done by himself with three assistants.

"I have said that the utmost simplicity met the eye everywhere in point of outward show; but it will be still more surprising to learn that there was not one photograph framed and hung upon the walls—no reception room. In his own sitting room there could be seen on the table two or three albums, large size and of the old style, of which the leaves were covered with prints, carelessly pasted, unfinished, untouched, unburnished, unanything, in fact; complete bareness, as much as to say, 'I am here, and that is sufficient.' Indeed it was quite enough, and no more seemed to be expected by his illustrious patrons, who, while admiring the great talent of the artist, could overlook his peculiarities and be fully satisfied with having seen some friend's portrait. I was naturally inquisitive as to the ways and means of arriving at such perfection, and my questions were of the usual kind: Who is the maker of your lens (he had only one, a four-inch)? He answered me with a benignant smile and a slight shrug of his shoulders. 'Lenses are like fiddles, my dear sir; it is not the instrument that matters much, but he who plays upon it that makes all the difference.' He was good enough to show me some of his negatives, which, from the

bluish-black lines of them, seemed as if developed for the second time with bichloride of mercury; they were rather thin, but very uniform and clear. His 'retoucher' was an artist and an engraver by profession, and he had acquired an admirable and intelligent proficiency in the method of improving and finishing the negative without spoiling it.

"It is not always within the power of every one of us to achieve eminence or many of our cherished dreams, but it is within the sphere of all to strive and to show that we take to heart the paternal advice of our Editor—aim high

VENTILATING DARK-ROOMS.

BY JAMES CHINN.

I HAVE noticed from time to time the various plans adopted for allowing the operator to inhale fresh air while at work. The plan I am about to describe is simple and inexpensive, and doubtless practicable in most studios.

In the first place, cut a hole in the wall (opposite the door, if possible) any convenient size, get two long strips of wood one inch square, and two others two inches by one inch; nail one of the flat pieces to one square piece, so as to form an angle or rabbet, nail this to the wall about two inches above the hole already cut, nail the other two together and then to the wall below the hole. Be very careful to have them parallel, or you will spoil the job. Make a piece of flat wood, a little longer than the hole, and wide enough to run easy in the two pieces nailed to the wall; put a few small staples in the wall around the room, and one each end of the shutter, and inside the top corner of the door; then take a strong string, or small copper wire, shut the door, make fast one end to a staple in the shutter, pass it through the staples in the wall, and fasten to the door, then through the staples along the other side of the wall; and finally, fasten the other to the other end of the shutter, open the dark-room door, and you will feel the benefit of the hole in the wall.

If you line the shutter and slides with a piece of cloth, there will be no danger of actinic light entering.

This may seem a lot of trouble, but if your dark-room be made of wood (which, luckily, most of ours are, in the Colonies) and you have any mechanical skill, it will not take more than an hour.

Blenheim, N.Z.

NORTHERN NOTES.

BY JO VESTRIS.

Hot Water Heating, versus Hot Air Heating.—At the last meeting of the West Riding of Yorkshire Society the President settled the question of heating the studio rather summarily, and yet with an air of reason quite satisfactory to the members.

The question as to the cause of moisture on the inside glass of a studio was answered by Mr. Haworth in rather an ambiguous manner. "In warming a studio with hot water, the air is charged with moisture, which is condensed, evaporated, and recondensed, and thus the room remains constantly wet." I should like to ask Mr. Haworth how he can get moisture from a hot-water pipe other than by boring a hole in the pipe and allowing the water to evaporate in the shape of steam?

"If the room were heated by hot air," says Mr. Haworth, "the constant influx of hot air forced out the same quantity from the room, which carried away the moisture with it." Now I say hot air cannot force out damp air any sooner than a cast metal pipe heated by water can. If free ventilation does not exist, condensation will take place by any heating system. The system of hot water heating by circulation is certainly by far the simplest, safest, and best when properly applied; and now that carbon has become a staple branch of the art science, this is the only system by which a regular supply of hot water can be had without in any way dis-

arranging the heating system. It is less liable to cause condensation than the hot air system, for the simple reason that hot metal pipes import no moisture into the studio, while hot air is just another name for steam, theoretically called dry air, a thing which is not known to exist in nature, and is very probably not producible in art.

Artificial Light.—I have been thinking over the many disadvantages (or *negative* advantages, if you will allow me) of the newly-brushed-up night-light craze, when I read in the daily paper that "pictures produced by artificial light are superior in many respects to those taken in the middle of summer," with the further advantage that "ladies and gentlemen can be photographed on their way to or from the theatre or ball-room. Isn't this too awful, that photographers can condescend to wait about the streets during the witching hours of night with their artificial light box and cyclopean eye, that ladies and gentlemen may be photographed "on the way to or from the ball-room or theatre," and further "sittings will be taken any hour of the day or night"? Now, artificial light is very good in certain circumstances, but the photographer who advertises in the above style—and it is a fact—must be aware that he is grossly perverting the truth in the first part, and sorrowfully degrading the profession in the second. The man who uses artificial light so largely should be relegated to the companionship of undertakers and firemen, who have a night bell attached to their doors, and who always go to bed in their boots.

At the next Photographic Exhibition we will be having these "artificial" artists coming out after Whistler, in "Arrangements" in three shades of grey, "Nocturnes" in pink and spangle with footlights, and "Symphonies" in dark-room and dormitory.

ARTISTIC PHOTOGRAPHY.

On many of the boulevards, and on all the chief streets in Paris, are found pretty shops where they sell nothing but photographic pictures.

During the Exposition an unusual display is being made. Everybody finds pleasure in examining the attractive exhibits found in these shop windows. Throngs are about them all the afternoons and during the evenings; as they light up brilliantly, real crowds. Such artistic pictures of actresses! Such clear and sharp pictures of the wonderful buildings in the public squares, and such views of the Exposition! Just out of the Rue De l'Opera, in the Boulevard Des Italiens, is one of these picture stores. We often looked in the windows, and one day saw, O, such a face! 'Twas that of a Madonna. Everybody looked at it, spoke about it. The dearest cabinet photograph sold in Enrope is that of Queen Victoria, taken by Bergamaseo; price, 75 cents, everywhere the same. The price of this Madonna was 90 cents. It seemed like a familiar face, a photograph which we had seen in New York; but it was on a card with the name and address of this Paris establishment. Several Americans had been heard to exclaim, as in the crowd we looked and admired together, "Oh! that's a picture." "Oh, what a photograph that is!" "Ah! if our American photographers could only take such pictures!" "Did you ever see anything anywhere so fine?" One day, after hearing these expressions; for the hundredth time, making up our minds to "*see*" about that, we went in to the shop and said, "Now be frank about that photograph; is it not made in the United States?" The Frenchman answered, "Oh, Monsieur, he is such bootifful picture! Ze artists he raves, Oh, ze bootifful Madon!" "But isn't it made in the United States? And didn't you get it through Anthony's?" "And isn't it one of Sarony's?" "Let me assure you, Monsieur, it is ze finest photograph in ze world!" And then the fellow went into a dozen exclamations as to the perfection of the artistic effect, the light, the shade. It took a long time, but to persistent questioning at last he said, "We, we, Monsieur; he is Sarony; he is Anthony!"

To get "good photograph," however, you must go to Paris; and "if American artists could only take such pictures," it would be so much more to our credit?

The face was that of Maud Branseombe, and the photographer was Sarony, of Union Square.

Look out for pictures taken over unmounted or stripped from the home card and remounted again. Beware of artistic photography in Paris.

[The above is signed by S. C. P., in *Anthony's Bulletin*. There are, we fear, tricksters of the kind descended all over the world. But does not S. C. P. indulge a little in "spread-eagleism?" Sarony can scarcely be called an American photographer, and Maud Branseombe is an English girl. The United States abound in pretty girls and capable photographers, so that no mistake is necessary to vindicate American claim to art and skill. And did the Frenchman really indulge in stage broken English?—Ed.]

Correspondence.

MUFFINS AND PHOTOGRAPHY.

SIR,—Would you kindly insert the following in reply to the Ramsgate paragraph intitled, "Hard Times," in your issue of the 21th of January? I beg to state that your correspondent has made a great mistake respecting the donkey and photographer's barrow which he met in St. Lawrence the Sunday previous. He states that, to his great surprise, he read, in yellow letters, "H. Griggs, Photographer, Wholesale and Retail Muffin and Crumpet Manufacturer." I beg to state that there is no such word as "photographer" on the barrow, nor the word "manufacturer," but in large capital letters the words, "James Griggs, Muffins and Crumpets, Wholesale and Retail, Ramsgate." The colour, instead of being yellow, is black and red. His eyes must be getting bad indeed not to take a better focus of the photo. barrow, both respecting colour and words. I have a vacancy in my establishment, and I think it would greatly improve our worthy friend's sight if he was to accept of it for the remainder of the season, providing he brings his own donkey and barrow, and sells substance for the winter; and may his shadow never be less!—I am, sir, yours respectfully,

JAMES GRIGGS,

Photographer, and Muffin and Crumpet Baker.
4, Albert Road, Ramsgate.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on Thursday evening, the 30th ult., at the Free Library, William Brown Street, Mr. H. A. WHARMBY, the retiring President, in the chair.

The minutes of the annual meeting were read and confirmed. Mr. H. G. Wood was elected a member of the Association.

Mr. THOMAS CLARKE, the new President, then took the chair, and, after thanking the members for appointing him their President, read his address (in our next).

THE PRESIDENT exhibited some prints printed by electric light, which had all the appearance of sun-printed pictures, and a print from an instantaneous dry plate collodio-bromide, taken by Mr. Sayce in 1863. Some transparencies were also shown on collodio-bromide plates, which had been prepared five years previously, and had since been carried in a deal grooved box about 9,500 miles without showing any signs of deterioration.

Mr. O. R. GREEN exhibited some panoramic views of Athens, an enlargement, and a large number of prints which he had taken during his travels, all from collodio-bromide plates.

Mr. GREEN, in reply to a question whether he had had many failures, said that the few he had were chiefly owing to the bad glass used, and not to the preparation of the plates. He (Mr. Green) also exhibited some prints toned about twenty-one years ago with gold and platinum. These had not faded at all, and he thought the whites were purer than the prints of the present day.

The Rev. H. J. PALMER then read a paper on "Portraiture by Artificial Light for Amateurs" (in our next), and afterwards exhibited his simple apparatus by giving a practical demonstration of his method of artificial lighting by taking a portrait of the President on one of Swan's dry plates.

A hearty vote of thanks was passed to Mr. Palmer, and the meeting was then adjourned until the 27th instant.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE above Association held its annual meeting on Wednesday, 29th January, at 160A, Aldersgate Street, E.C. The chair was taken by W. S. BIRD, Esq.

The business of the evening was commenced by reading the minutes of the previous meeting, which were confirmed.

The Secretary's report was then read to the meeting as follows:—

Secretary's Report.

"In presenting my statement for the past year, I have the pleasure of reporting an improvement in the condition of the Association.

"The receipts for the year are £39 7s. 6d. as against £35 13s. 4d. of the preceding year, and the actual working expenses £22 15s. 1d. as against £26 9s. 2d. Therefore, in consequence of the increase of receipts and decrease in expenditure, the funds of the Association have been raised from £17 3s. 10d. to £57 16s. 3d.

"This result I submit is satisfactory, and should the Association receive that support which it deserves from photographers, the funds would soon be multiplied, and thereby the operations of the Association could be considerably extended."

Board of Management Report.

"The board of management offers its sincere and hearty thanks to those gentlemen who have so kindly, by their donations and otherwise, assisted the Association during the past year, and it hopes that with a continuance of this assistance the designs of the Association may be still further promoted.

"Although, perhaps, from a pecuniary point of view, the Association is as yet not in quite so flourishing a condition as might be desired, yet, looking at its career from its commencement up to the present time, it has probably never been in so healthy a condition generally as now.

"Its pecuniary state, too, though it might certainly be better, is improving. A glance at the Secretary's report will show that during the last year the receipts have increased slightly, while the expenses have been lessened.

"All that is now required to make the Photographers' Benevolent Association an active and flourishing institution is the thorough support of photographers generally throughout the kingdom, and the Board has permission to publish the two following letters selected from similar correspondence in support of this view.

"71, Terminus Road, Eastbourne.

"SIR,—Herewith please find cheque for one guinea for your funds, and we are very sorry to see so small a balance to your credit. If every English photographer sent you just the value of one dozen of their C.D.V. pictures, it would greatly increase the total of an institution that, we think, is very much needed, and little thought of by many masters.—Yours truly,

"G. AND R. LAVIS."

"19, Bloomsbury Street, W.C.

"DEAR SIR,—In reply to your application I send you enclosed another donation of £3 3s. I do hope the Association will be self-supporting in another year. Efforts should be made to secure a greater number of members. Surely the journals will help you in this! A few lines on the advantages of your Association oft repeated would, I should think, bring about the desired result. I can but repeat my hearty good wishes for the prosperity of the Photographers' Benevolent Association, and remain yours faithfully,

"J. H. DALLMEYER."

"The advantages of such an institution are widely felt, and this Association has already been the medium through which a considerable amount of distress has been relieved, and a large number of photographers assisted in various ways. If masters and men would come forward heartily, and assist the Association in its charitable purpose, its usefulness might be very considerably augmented.

"The Association not only relieves members when in distress,

but also affords them all possible assistance in obtaining situations when out of employment.

"Subscriptions are as follows:—Ordinary membership, yearly, 10s. 6d.; half-yearly, 5s. 6d.; quarterly, 3s. Honorary subscriptions, one guinea per annum.

"At the close of the year a soiree was held at the Exhibition, Pall Mall, the Photographic Society of Great Britain having kindly given the use of their Room, and the receipts being devoted to the funds of the Association. The attendance was good, and the evening went off very successfully. The President and Secretary of the Society were both present.

"The Society also desires to record its sense of the courtesy and consideration of the photographic journals in giving its proceedings a desirable publicity.

"In conclusion, the Board of Management would point out the necessity of the active support of all members if the ultimate success of the Association is to be secured. Every effort to further the aims of the Association, and to make known its existence and intentions, may certainly be considered work in a good cause.

"W. S. BIRD, Chairman."

The two reports were adopted by the general meeting.

The election of officers then took place. Messrs. Moore and Platt were elected as ordinary members of the Association.

A letter from Rev. F. F. Statham was read to the meeting, stating his inability to be present through ill-health. The Secretary was instructed to express the regret of the General Meeting to hear of his illness.

The business having been brought to a termination, Mr. Bolas proposed, and Mr. Ashman seconded: "That this meeting present a vote of thanks to the Chairman for his very able services during the year." This was carried unanimously, and the meeting dissolved.

The next committee meeting will be held at 8 p.m., on Wednesday, March 5th.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY. The Association met on the 20th December, 1878, Prof. H. VOGEL in the chair.

After the admission of a new member, Herr RELVAS, of Collega, near Lisbon, a member of the society exhibited some portraits from nature in colotype, which were pronounced by all present to be remarkably successful specimens of the process, showing unusual intensity and depth.

Dr. FRIEDLANDER proposed that all patent specifications relating to photography should be acquired for the use of the Association, and it was determined to purchase those which had special interest for the members.

A letter was read from Messrs. FREY & Co., of Aaran, Switzerland, declaring that the so-styled rapid process which Herr Schwartz had lately offered for sale to the members of the Association was merely an old method described and published in the year 1861, by a photographer of Munich. As a proof, they instanced the case of one of their own customers, who in that year had bought precisely the same formula and directions for eighteen florins, and on his remonstrating with Herr Schwartz, had received the price of his second purchase, fifty marks, returned to him, with the excuse that the latter had been co-inventor of the Munich process.

Herr MAROWSKY made some remarks on chrysoïd varnish, whose yellow colour he maintained to be very unstable. According to his own experience, it had considerably faded after being in use for a couple of days.

Herr SCHAARWACHTER had made the same observation, and was of opinion that this varnish, of which so high expectations had been formed, would be found to be valueless for photographic purposes.

Dr. VOGEL read a report of the Polytechnic Society on the patent polychromic autographic process of Herr Holtzmann, of Spoyer. It was claimed for this process that by means of it from twenty to thirty good copies of a many-coloured drawing or water colour could be produced by mere contact, without the use of any press; it was also expected that the process would supersede every kind of tracing or reprinting process, and would make the ordinary mercantile copying book quite unnecessary. Without accepting all supposed superiority, the chairman acknowledged that the invention had some merit, and was in a position to demonstrate the method to the meeting. The original drawing, which may be either in outline or mass, must first be prepared on tracing paper with special (aniline) colours. A piece of paper—called by the inventor negative paper—is

coated with a gumlike substance, floated for a couple of minutes on water, and then blotted on filtering paper. By this means the surface of the paper has become sticky; the original is laid on it, mado to adhere by pressing with a handkerchief, and then drawn off again. On the negative paper is now produced a copy of the original in the same colours, only the copy appears to be much more brilliant and intense than the original. This copy, called by the inventor, not quite correctly, a negative, serves as a printing plate. Pieces of ordinary paper are damped and laid on the negative, and when removed have imprinted on them an accurate copy of the original. The first copy taken in this way at the meeting showed all the colours equal in intensity to those of the original; in the second they were decidedly fainter; and in the third some of them quite failed to appear. Prof. Vogel expressed a decided opinion that it would be impossible to take anything like the number of good copies by this process as are claimed by the inventor. He showed the copy of a letter which he had written in different colours on ordinary instead of tracing-paper; of these, only two, violet and dark green, came out well, the majority failing to copy at all. The meeting came to the conclusion that the method, though highly interesting, was hardly likely to become of practical importance.

The next meeting was held on the 3rd of January, 1879, when Dr. VOGEL again occupied the chair.

A letter was read from Herr Reutlinger on the fading of carbon prints. He had carried out a variety of experiments with a large number of samples of tissue, in which he had carefully attended to all the precautions suggested by his own experience as well as by the instructions of others, so as to overcome all technical difficulties of the process. But in the durability of the prints thus obtained he had been bitterly disappointed. During the late exhibition he prepared some carbon prints with the greatest care on tissue obtained from the well-known house of Braun and Co., and exhibited them in the same case with a number of silver prints. After being thus exposed during the whole period of the Exhibition—from six to eight months—the difference in the condition of the silver and carbon prints was most marked. The latter, when first exhibited, had a rich brown tone, but when they returned to the studio they had a dirty yellow tint shot with green, and had lost much of their original intensity; spots that had been retouched had become painfully manifest. During all this time the silver prints that had been exposed under exactly the same circumstances had remained unchanged. Herr Reutlinger believes the cause of the change of colour to be due to chemicals contained in the colouring material of the coating, or in the paper. His opinion is that the old silver process, if attention be paid to it, will long continue to bear the palm.

Herr MAROWSKY agreed with Herr Reutlinger in considering silver prints much more durable than those in carbon. He possessed some of the former twenty-five years old, which were now as good as new in point of colour. They had, however, been kept unmounted.

Herr JOOP remarked that unmounted copies were more durable than mounted ones, especially than those mounted on card.

Herrn ROLOFF and REICHLARD had had similar experience of the superior durability of unmounted photographs, but the latter gentleman was unwilling to admit that carbon prints are so liable to change colour.

Herr QUIDDE, while acknowledging the correctness of the observations of Messrs. Reutlinger and Marowsky, appealed to the well-known chemical facts, from which it followed that silver prints are much more easily affected than carbon prints, and that the fading, when it had once commenced, went much further in the former than in the latter. On this ground he believed that photographic copies of documents that might preserve their importance for centuries should be taken by a process resting on an imperishable material like carbon.

Professor VOGEL explained that carbon pictures that had been prepared on tissue tinted with Chinese ink or lamp-black would not fade. The cause of the change of colour experienced by Herr Reutlinger was to be found in the use of carmine, which is known to be an impure and cyanescent colour. Insufficient washing might also, in consequence of a residuum of chromate, produce a change of tint in carbon pictures. To obviate this, the treatment of the print with sodium hyposulphite to decompose the chromate could be recommended. The speaker had twelve years ago prepared his own tissue, and on the advice of the late Herr Grasshoff had used Vandyke red prepared by Moewe, of

Berlin, instead of carmine. Pictures taken on this tissue had not suffered the slightest change of colour in all that time.

Herr HARTMANN presented to the Association, in the name of Herr van DELDEN, of Breslau, a number of large photographs—mostly of interiors—which met with unanimous approval. Herr Hartmann was unable to describe the objective with which these pictures had been taken, but the evenness of definition and the amount of detail, both of which had excited admiration, he accounted for, the former by the use of diaphragms, the latter by their having undergone long exposure, amounting in some cases to an hour and a-half.

In reply to a question of Herr Reichard, Herr Hartmann explained that Herr van Delden possessed no special process for obtaining such purity and equality of definition with so long an exposure; all that he did was to use a good fresh silver bath, and to line his slide and camera with damp blotting-paper.

Dr. VOGEL pointed out that the measures to be adopted when long exposure is required had often been discussed in the Association. Among these are the addition of glycerine to the silver bath, or, preferably—as the latter might spoil the bath—flowing a solution of silver and glycerine over the plate after it has been silvered; also an after-silvering of the plate in a weak bath. Again, moistening the interior of the camera had been recommended; further preventing evaporation, as far as possible, by placing a piece of plate glass in front of the plate to be exposed, and separated from the latter only by spots of sealing-wax at the corners.

Herr JOOP had also occasionally to expose for an hour and a-half, and had resorted to no other precautions than that of resting the plate with its lower edge on a piece of blotting-paper, and of rubbing the back of the plate perfectly dry.

The CHAIRMAN read a letter from Herr von Schlicht, in which he gave an account of the successful results he had obtained in the dry process with gelatino-bromide emulsions prepared according to Stuart Wortley's instructions. In drawing attention to the extraordinary purity and delicacy of the photographs sent by the writer to accompany his letter, as samples of the work that he had accomplished with this process, Dr. Vogel expressed his gratification that such excellent results had been obtained with gelatine emulsion plates prepared in Germany. He himself had been continuing his experiments with English plates. With new ones just obtained from Swan, he expressed himself as disappointed as regards their sensitiveness, but some lately received from Wratten and Wainwright had given astonishing results; he had been able with the latter to work eight times as quickly as with wet plates.

Herr SELIGMANN, who had also ordered plates from England, had met with an unfortunate accident on their arrival in Germany. When passing the Custom House as glass the officer had insisted on opening the package, and, admitting the light, had spoiled them. By immersing them in a bath of 16 parts potassium bromide, 50 parts nitric acid, and 350 parts water, Herr Seligmann had succeeded in restoring to a certain extent their sensitiveness.

Some negatives executed by Herr PRUMM with Wratten and Wainwright's plates, and taken from the one exhibited, they appeared to give a large amount of detail, but seemed somewhat weak, so that it was astonishing to find such good prints taken with them. In reply to a question, Herr Prumm stated that printing from these negatives took four times as long as for ordinary wet ones; but he had hopes in time to overcome this difficulty. The weak appearance of the negatives, as well as the long time required for printing, he attributed to the exceeding sensitiveness of the plates causing them to veil slightly in the dark-room, though he had employed every precaution.

Herr SELIGMANN gave an account of his experiences with Wilde's plates. With an ordinary wet plate he employed an exposure of two seconds, while to obtain the same effect with one of Wilde's dry plates he required an exposure of thirty seconds, and that, too, when it was developed soon after being exposed. When a similar plate was developed six weeks afterwards, it required an exposure of 120 seconds. Dr. Vogel pointed out that the best way to proceed for photographers who prepare their own plates, and import the gelatine emulsion from England, was to order the gelatine films to be sent to them in a letter; they could then dissolve the latter in water and coat their own plates with the solution.

Dr. VOGEL, to the great pleasure of the members, expressed himself as ready to undertake a course of lectures in chemistry for the benefit of the members of the Association. He had now been able to make time for carrying out this proposal, and hoped to be able to meet the wishes of all concerned.

Talk in the Studio.

THE *Athenæum* says:—"Mr. H. B. Pritchard, the author of 'Dangerfield,' has a new novel in the press, called 'Old Charlton.'"

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Annual Meeting of this Society will be held on Tuesday evening next, February 11th, at the Gallery, 5A, Pall Mall East, when the election of officers for the ensuing year will take place and other business be transacted. Mr. John Harmer will exhibit and explain a new camera for the studio.

SUNSHINE IN LONDON.—The Astronomer-Royal has just published his report of the amount of sunshine with which we were favoured in the neighbourhood of London during the year 1878, and it must be owned that the result is dispiriting, and almost justifies the criticism of foreigners that we English so seldom see the sun that we hardly know him when he makes his appearance. Things are not quite so bad as this, but it is bad enough to know that, during the year, out of 4,454 hours of possible sunshine, we only had 1,250 hours in the neighbourhood of London, or a very little more than a quarter of the amount which we should have had had the sky been perpetually cloudless. In London it is probable that the sunny hours were considerably shorter than even this record gives us, for it is frequently fine and sunny even at Greenwich when we are enveloped in fog and darkness here. Were we to take the winter months only, it would be seen that the visits of the sun are indeed few and far between. The last week of which we have seen a return gives only one hour and a quarter of sunshine, and we have not had more than one fair day of sunshine during the whole month of January. It is probably not too much to say that in the four winter months, that is from the 1st of November to the end of February, Londoners do not receive one week's sunshine, a minimum which, we reluctantly admit, fairly justifies the sarcasm of foreign visitors at our English climate.—*Standard*.

LIGHT AND LIFE.—The question as to how life is affected by the different colours of the spectrum has at various times engaged attention, and plant life has apparently been more studied in this respect than animal. Two distinct series of researches lately described to the French Academy seem to afford some fresh insight into the matter, and it is interesting to compare them together. One series, by M. Bert, was on plants; the other, by M. Yung, on the eggs of certain animals. M. Bert kept plants within a glass trough enclosure, containing an alcoholic solution of chlorophyll (very frequently renewed) and exposed them thus in a good diffuse light. The solution, which was very weak, and in a very thin layer, intercepted little more than the characteristic region of the red in the spectrum. This excluded part, then, was proved to be the indispensable part of white light, for the plants immediately ceased to grow, and before long died. It is in this red region (as M. Timmizzeff has lately shown) that the greatest reduction of carbonic acid takes place. If red rays are kept from the leaf the plant can no longer increase its weight, it is reduced to consuming reserves previously accumulated, exhausts itself, and dies. This part of the spectrum, however, though necessary, is not sufficient. Behind red glass plants may no doubt live long, but they get excessively elongated and slender, and their leaves become narrow and little-coloured. This is owing to the absence of the blue violet rays. Thus each region of the spectrum contains parts that play an active role in the life of plants. Now turn to animals: M. Yung has experimented during three years on the effect of different spectral colours on the development of the eggs of frogs (the common frog and the edible frog), of trout, and of fresh-water snails. It was found that violet light favoured the development very remarkably; blue light comes next in this respect, and is followed by yellow light and white light (which two gave nearly similar effects): On the other hand, red and green appear to be positively injurious, for it was found impossible to get complete development of the eggs in these colours. Darkness does not prevent development, but, contrary to what some have affirmed, retards it. Tadpoles of the same size, and subjected to the same physical conditions previous to experiment, died more quickly of inanition when deprived of food in violet and blue rays than in the others.—*Times*.

PYROXYLINE AND NITRATE OF AMMONIA.—A remarkable accident happened a few weeks ago at l'École Normale to M. Zédé, who was studying the properties of a composition formed of equal parts of gun-cotton and nitrate of ammonia. This was inflamed in a bronze tube of 6mm. internal diameter, and expanded without detonation. Thirty experiments had been

mado, and M. Zédé then reduced the size of the tube to 5mm. When he tried the experiment anew under these conditions a frightful explosion occurred. The tube was shattered into sixty pieces, some of which passed through the roof of the laboratory and penetrated about 4 ctr. into a brick wall. The operator had one of his legs broken.

To Correspondents.

H. W. A.—It is not customary for photographic publishers to purchase negatives; they prefer to be supplied with the prints of anything worth publishing. But the possibility of the sale of negatives chiefly depends on their excellence and the interest of the subjects. Mr. F. Frith, of Reigate, sometimes purchases negatives of the subjects and quality sent him.

J. SIMPSON.—The mode of enlargement upon which you wish for information is in our view the very worst method you can adopt, and the most difficult to work so as to secure good results. The simplest and best is to make an enlarged negative and print from it. The next best is to produce an enlarged collodion print and transfer it. To produce good direct enlargements you should have a solar camera, and work with direct sunlight. You may produce direct enlargements with a magic lantern and magnesium wire, or a "line light"; but you cannot hope to produce direct enlargements by ordinary day-light. You can purchase iodized paper, with instructions for silvering, of Mr. Solomon, Red Lion Square; or you may prepare paper for yourself, using either *Rive* paper or drawing-paper. This must be salted with a solution containing four grains of chloride sodium and four grains of bromide of ammonium in an ounce of water, and excited with a forty-grain silver solution, exposed wet, and developed with a saturated solution of gallic acid. In response to your request for advice, we again advise you not to attempt an obsolete method, as a better exists.

W. GRIFFITH MEDBY.—The "Carver and Gilder's Guide, and Picture Frame Maker's Companion," published by Kent and Co., Paternoster Row, price half-a-crown.

TAYLOR (Northwich).—We regret that we cannot give you information of any value. We can only repeat and emphasize the advice recently given in our columns, not to send cash and negatives to unknown persons without some satisfactory reference. You cannot do anything with your lens, and you may risk injuring it. A lens of shorter focus will be much quicker, as well as better in every way. It is very difficult to get brilliant images with twenty-four feet between lens and sitter in the kind of atmosphere often prevailing in this country. Such a space of slightly misty atmosphere gives a dull foggy character to the picture.

AMATEUR MECHANIC.—You may stain deal or other light-coloured woods black in various ways. One which will give you least trouble consists in the use of "Stephens' black stain," which can be purchased of most oil and colourmen. Or you may use a solution of sulphate of iron, and follow by a solution of gallic acid. Or boil a quarter of a pound of logwood chips in a quart of water, add a handful of walnut peel, and boil again, remove the chips, and add five ounces of vinegar. 2. You will require a mitring block to cut the corners of moulding sufficiently true to form a good joint in a frame.

G. T.—A strong developer is often useful in cold and dull weather in bringing out an image almost impossible to develop with a weak solution. We should call a 50-grain solution of iron strong. It need not have more than twenty minims of acetic acid.

PERPLEXED.—Another case of imperfect fixation. Remember that a solution of hypo quite strong enough for perfect fixation in summer is useless in winter. But it is of more consequence that the solution should be made warm, that is, to a temperature of 60° Fahr. If a solution of hypo be freshly mixed, it will be found very cold, as the process of solution materially lowers the temperature. In winter, always mix it with warm water. It is wise to maintain the temperature of the dark-room to somewhere not much below 60°, certainly above 50°.

C. J. HALE.—We have indicated to the Publisher certain numbers containing hints on photography and wood engraving, or on producing photo-lithographic transfers which may be transferred to wood instead of stone. Some other numbers of a date long back are out of print. In other cases, incidental information occurs in articles devoted to other subjects. It is somewhat difficult for an amateur to obtain specific information on a particular subject without the general study and reading which is involved in a full knowledge of the art. We shall have pleasure in helping in any special difficulty you meet in your experiments.

ANXIOUS.—The pyro developer is much the best for collodion transfers. You may try twelve grains of sulphate of iron in an ounce of water and twenty minims of acetic acid. This will answer, but not so well as the pyro developer.

HARRY POINTER.—Thanks. But it is better not to re-open the matter, even to mention that amusing fact. Several Correspondents in our next.

The Photographic News, February 14, 1879

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE BANK OF FRANCE AND PHOTOGRAPHY—INTENSIFYING FORMULÆ—THE COMPARATIVE PERMANENCE OF CARBON AND SILVER PRINTS.

The Bank of France and Photography.—It is said that at the bank of France they have recently instituted a photographic studio in the cashier's department. The studio is in the rear of the desks at which payments are made, and the consequence is that any customer's face is readily seen when he comes up to draw his money. It is not likely that the fact is unknown to those who frequent the bank; but, after all, this is of little importance. It is not the portraits of those who come every day that are wanted, but the stray sheep who occasionally come within the bank doors. The bank clerk, when he is at all suspicious, communicates by signal with the photographer in rear, and to give the latter time to focus and operate, care is taken to delay the model's departure as long as possible. There is little fear of moving, for a customer, when he is intent on a bank-clerk counting money or sorting notes, is not likely to fidget about much. At the same time, a very ready photographer is wanted. His camera would, no doubt, be properly swung so as to be capable of taking the range in a moment; and if he employed a dry rapid gelatine plate, there would not be such necessity for delay. The plate would already be at hand in the dark slide, and a single movement would suffice to replace the focussing screen by the sensitive film. Perhaps, however, the bank has instituted the studio more as a deterrent than a detector of crime. If it gets bruited abroad that there is a photographic detective on duty inside the bank, the fact will have the same effect, probably, as the warning about "spring-guns and man-traps" exerts upon trespassers. We know that the custom of photographing officials and servants in companies and associations is one that acts as a great deterrent from crime, and, no doubt, causes many a wavering spirit to keep on the right path, instead of turning down the wrong one. In Paris, it is said, all policemen are photographed, so that a record of their features may remain with their superiors, in the same way as criminals are, so that the police-picture galleries must be very extensive indeed.

Intensifying Formulæ.—Sulphide of potassium has recently been advocated in Germany as a body for intensifying negatives, and, no doubt, it may be employed with advantage in this connection. But photographers should use some discretion in the choice of their intensifiers. When a negative is wanted with transparent lines and a ground as "black as your hat," for the purpose of photo-lithography, or other similar method, there can be no doubt that you cannot get too opaque a film. Under these circumstances, the Eder and Toth intensifier, which we have frequently published in these columns, and which consists in the use of nitrate of lead, red prussiate of potash, and ammonium, is one of the most effective. The light—even summer sunshine—fails to penetrate the sooty film produced, while the lines remain quite clear and transparent. Bichloride of mercury and ammonium also give a dense film, though not such a satisfactory one; while the bichloride followed by hyposulphite, and, therefore, without any ammonium, will likewise be found useful when intensification is not to be pushed to extremes. The employment of bichloride of mercury alone is, in fact, exceedingly convenient where washes or surfaces of different gradations are to be reproduced. Sketches, or drawings which have been washed in, and which do not, therefore, present any extremely delicate half-tones, may be reproduced very completely by treatment of the negative with bichloride followed with hypo, whereas subsequent dosing with ammonium would affect the lighter gradations.

The Comparative Permanence of Carbon and Silver Prints.

—The well-known Paris portraitist, Reutlinger, has brought before the German Photographic Society the question of faded photographs. He makes a very singular statement. He tells us that he was represented at the Paris Exhibition both by carbon prints and silver prints. They were shown upon the same screen exhibited side by side. When first exhibited, they were, naturally enough, perfect in their character; but at the close of the gathering there was a marked difference between them. The silver prints were still fresh and full of tone, the carbon impressions showed marked signs of change. The latter, when first exhibited, we are assured, "had a rich brown tone, but when they returned to the studio they had a dirty yellow tint shot with green, and had lost much of their original intensity; spots that had been retouched became painfully manifest." The silver prints, on the other hand, we are informed, remained exactly as they were at first. After M. Reutlinger's communication had been read, M. Marowsky told the meeting that he agreed with that gentleman in considering silver prints much more durable than those in carbon. He possessed some of the former, twenty-five years old, which were at the present day as good as new in point of colour. We are glad to see that afterwards a good deal was said on the other side, and Dr. Vogel, the President, very firmly assured the meeting that tissue properly prepared with Indian ink or lamp-black could not fade. The change of colour was to be found in the carmine, he said; and one would have thought that most photographers who had anything to do with carbon printing were fully aware of the fact. It is a very singular thing if M. Reutlinger finds carbon prints fading beside silver prints which do not, but it is nothing more. There are pigments which fade, and pigments which do not fade, and according as you use one or other in your tissue, so will this retain its colour. There is nothing more to be said on the subject. That silver prints produced five-and-twenty years ago are said to be seen as fresh and full of tone as when first prepared is likewise no novelty. Many of us have albums at home that demonstrate beyond a doubt that silver impressions can be secured of a durable character; but the fact proves nothing. We know that a film of silver is a very delicate thing, nevertheless, and that sulphur and albumen in combination with it are bad things to have in a picture. If to-morrow we could produce by pigment printing pictures as bright and beautiful, as likewise as readily and inexpensively, as by the silver process, we make bold to say that there would be little silver printing done. M. Reutlinger complains that the tissue upon which his prints were produced emanated from the well-known firm of Braun, of Dornach, and that the pictures, blooming enough at first, lost their colour after eight months' exposure to light. Not only this, but they appeared of "a dirty yellow tint, shot with green." How this could have happened, even with a fugitive pigment, is more than we could understand; but M. Reutlinger believes the change to have been due to "chemicals contained in the colouring material of the coating or in the paper." Doubtless the transfer paper turned yellow, as we know it will, and the bloom of the carmine faded, but still the green markings are incomprehensible. The retouching marks which became apparent would not have been visible if the precaution had been taken to retouch with some of the pigment mixture scraped from the tissue. But that some tissue supplied by Messrs. Braun and Company has faded, while some excellent silver work of M. Reutlinger did not—we say excellent, advisedly, since a Paris sun, shining for eight months, would be a crucial test—is no proof whatever of the durability of one class of printing, and the evanescence of the other. If photographers have by them silver prints which have not faded, they have plenty which have done so. It was remarked at the same meeting that unmounted silver prints were found to keep much better than mounted ones, and of this there can be little doubt.

since most cardboard is bleached with hyposulphite of soda, and contains a trace of that salt. Photographers should not forget this.

FINE ART COPYRIGHT.

THE *Daily News* gossips about the subject of copyright in works of fine art, without, however, expressing any definite opinions on the subject, except, perhaps, in so far as it is more fair to photography than is the press usually when such subjects are discussed. Here is the leader:—

The case of Ridley v. Tuck, which we reported yesterday, is not only interesting in itself, but happens to coincide with the agitation of the questions of property in works of art, and of the relations of different arts to each other. Photography, as Mr. Samuel Fry, who wrote to us a day or two ago, complained, has never been regarded with much affection by proficients in the higher branches of art. It has rendered immense services wherever accuracy for purposes of historic or scientific research is concerned. In its higher developments it has real artistic worth. It has made portraiture more faithful, and less flatteringly idealistic. The rather vague alarms which were formed, or at least announced, at the time of its invention, have not been verified by the result. The camera has not deprived artists of their livelihood, or turned the Royal Academy into the streets; it has not even, to judge from the appearance of the walls of Burlington House every May, interfered at all seriously with the business of the portrait painter. But while it has merits not always allowed to it, and has not the demerits which were sometimes laid to its charge, it has contributed to a branch of art which may, perhaps, be safely described as not the highest variety. Photography constantly helps to fill in the details of certain large and complicated works of art, reproductions of which appear to command a considerable sale. Everybody has noticed in the shop windows engravings and photographs of congresses, councils, and other collections of distinguished or undistinguished persons. The faithfulness of the likenesses in these cases is generally guaranteed, and yet a short reflection is sufficient to show that the gifted artist of the original painting can hardly have taken the trouble, or indeed have had the opportunity, to take the individual portraits in the ordinary way.

The case to which we have alluded will explain the mystery to those to whom it is still mysterious. Mr. Ridley is an artist, and has won his spurs, in the peculiar combination of arts which produces these pictures, by a group of the Royal Family. It occurred either to Mr. McLean, the well-known printseller in the Haymarket, or to Mr. Tuck, a photographer of some note, that a wider if not a higher flight might be taken, and that the Pan-Anglican Synod, with some eighty Bishops, might be "grouped." Mr. Ridley undertook the commission, and the little disagreements which thereupon occurred do not now concern us so much as the method of execution. Royal Families and Pan-Anglican Synods are, it appears, done with a facility which would surprise Rembrandt or Michael Angelo. As Mr. Justice Hawkins well described the process, "You draw a lot of bodies of different sizes, and then stick the heads on." The painter draws the bodies by guesswork, and photography afterwards supplies him with the heads. Three heads it seems are allowed for the size of the body, by which we must probably understand the episcopal trunk or portion covered by the apron, as distinguished from the limbs or portion covered by gaiters. When the eighty headless Bishops were properly grouped, eighty cartes-de-visite would, it may be presumed, be produced, and Mr. Ridley would proceed to sort his heads to his bodies as best might be. It must require a considerable knowledge of what used to be called political arithmetic to assort the bodies of eighty Bishops "sizeably" to their yet unascertained heads, and perhaps Mr. McLean's reluctance to complete his bargain arose from this cause. But the plan of composition—a word never more suitable than in this case—if it does no more, shows us how very difficult the question of so-called artistic copyright is. Suppose Mr. Ridley's picture to have been finished and the divorce (justified by the examples of Saint Patrick and Saint Denis) between the clerical heads and bodies to have been happily terminated, where could the copyright of such a picture reasonably reside? Certainly not in the heads, which, notwithstanding, must be regarded, at least from the public point of view, as not the least interesting part of the performance. Scarcely in the bodies, which, apart from the heads

would hardly be recognisable, and might be made to do duty for any other gathering which happened to include eighty members. Not many years ago there used to be a custom, by no means to be honoured, which on one occasion gave Thackeray annoyance enough to make him notice it in a "Roundabout." A gorilla, or some other unpleasant beast, was depicted, and for the countenance the photograph of some noted person was substituted. This method of caricature, which had for a time considerable vogue, appears to be closely german to the approved modern method of representing Pan-Anglican Synods, Royal Families, and such-like groups.

The correspondent to whose letter we have referred brings forward a claim on the part of photographers to copyright in all "artistic" portraits. The word is of course vague, but there really seems to be nearly as much ground for Mr. Fry's contention as for the claim of painters to reserve in all cases the right of reproducing, no matter by what means and however mechanically, the work of their hands. Mr. Fry, in effect, says:—I group my sitter, and expend my ideas in grouping him, and in taking and developing his portrait, and I don't sell him the right of reproducing those ideas." Something not at all dissimilar was said the other day at the Grosvenor Gallery. It is possible in both cases to see a certain amount of reason in the claim, but the weight of argument seems to be more against it in the painter's case than in the photographer's. For what the purchaser pays for in the case of a painting is undoubtedly the "handwork" of the artist—work which is not to be reproduced by any process which gives the least temptation to the pirate. A photograph may tell the story of a picture, but it can do little more; even the best engraving or an etching has rather other merits than the same. But there is no doubt that a photograph can be made with a little mechanical skill to resemble a photograph pretty nearly in the traditional relation of the two peas. The imitator thus picks the originator's brains, in exactly the same manner as the pirate of printed matter, reproducing his work and robbing him of his profits without any fresh expenditure of intellectual force. The same may perhaps be said of Mr. Ridley's *disjecta membra*, or at least *corpora*, of Bishops and other dignitaries. If such things can be multiplied indefinitely, as they certainly can be, a strict copyright law is almost the only chance their ingenious inventors have of deriving profit from them. The question between the photographer and the public is only one of the many puzzling questions to which the general question of copyright gives birth, and which become more and more puzzling as methods of mechanical reproduction are multiplied, improved, and cheapened. On the one hand, the public naturally desires to have its Bishops, headless or not, as cheap as may be; on the other, the artist or the dealer is equally naturally anxious for his profit. The case which is hardest for the photographer is undoubtedly the publication for profit of photographs originally taken, or understood by the artist to be taken, for the mere private use and enjoyment of the sitter. In such a case he receives, indeed, all that he covenants to receive, but finds himself unwillingly furnishing somebody else with a new and unexpected source of profit. The difficulty is not altogether unlike that of the parable which first sent Mr. Ruskin wandering in the paths of political economy. It is the gain of somebody else, and not the loss of the complainant, that forms the ground of complaint. Something of the same kind pervades the whole question of the claim of artists to the profits of the reproduction of their works, and the presence of this something perhaps explains the reluctance of persons like Sir James Stephen to give them any right whatever to such profits, or to compensation for abandoning them.

We subjoin the letter above referred to as appearing in the *Daily News*:—

"SIR,—In the account of the important meeting held at the Grosvenor Gallery, under the chairmanship of Sir Coutts Lindsay, I find both he and those who followed complained justly of the disadvantageous position in which artists find themselves from the difficulty of obtaining legal copyright in their works. Each speaker assumed that the photographer, described as "the owner of a box of chemicals," was in a far better position. Permit me to say that although as regards pot-boilers, ordinary publications, pictures, we are satisfied with the state of the law, yet when we look at what is now one of the most important, as it is also the highest branch of photography—the production of original works containing a distinct artistic idea—we are quite as badly off as the painter. Proprietors of illustrated papers

appropriate in the coolest possible manner art photographs, frequently re-naming them to suit their purpose, and never mentioning the photographer's name in connection with them. This Christmas, one illustrated paper published as a coloured presentation picture a photograph of mine without acknowledgment, and circulated several hundreds of thousands. In this picture was found just the difficulty referred to by Sir Coutts Lindsay. It was not alone a portrait, but it contained a distinct and original art idea; and the payment of a guinea by the sitter was never intended to give him copyright in it, or any right at all, except that of private presentation. The 'religious' papers are grievous offenders in this way, and their letters of explanation have been remarkable for hardness of assertion. The art claims of photography are now beyond doubt. In all exhibitions they are freely accorded positions in equality with other branches of artistic skill; and whilst at one time the stigma of want of art feeling was thrown at us, not without cause, the impression now is that photography is walking in rather too close contiguity with art canons to be entirely pleasing to some.—I am, faithfully yours,
SAMUEL FRY."

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

PRESIDENT'S ADDRESS.

We append the address (left over from our last on account of pressure on our space) of Mr. Thomas Clarke on his appointment as President in succession to Mr. H. A. Wharmby.

This is the fifteenth anniversary of the Liverpool Amateur Photographic Association. During the interval of its existence great changes have taken place in the practice and science of photography, and by the patient and unswerving industry of a host of ardent workers, this useful art has been brought to a state of perfection which, in point of utility, enables it to rank as one of the best-known and important sciences of the present day.

When we consider that it is not more than forty years ago that the germs of the photographic art were first brought to light, and that only twenty-eight years have elapsed since the advent of collodion and nitrate of silver bath, it is surprising that a science so small and unassuming in its beginning should have been able to have made such gigantic strides as that of photography.

It must be universally admitted that the influence of our art-science is now felt in every remote corner of the globe; and while the amateur, to whom the art owes so much, delights to make it his especial hobby and companion, and the professional his means of subsistence, the various governments of the world call it to their aid in collating facts with reference to geographical conditions of various countries, which, for strategic and other purposes, is found to be of the greatest reliability and value. In the copying of maps and charts it is largely used, especially by the governments of Germany and Austria; while in the medical world, particularly in the United States of America, it is brought into requisition as a means of recording various forms and stages of disease. The microscopist likewise uses it as a power to enable him to register in an enlarged form the interesting detail of insect and vegetable life, which for truthful delineation and delicacy of result, cannot be equalled by any other known means.

It will be found, on reference to the historical records of photography, that this science has progressed by four distinct stages. In the first place, there was the beautiful process given to the world by the genius of Daguerre, who, in the year 1839, exhibited in London a number of views taken in the French capital, which, for beauty of result, excited at the time the utmost curiosity and admiration. Strange as it may appear, this identical process was selected by the French government so recently as the year 1874 as the one best adapted to photograph the transit of Venus—an event in astronomical science considered to be of the highest degree of importance. Most other governments fitted out similar expeditions to proceed to different parts of the globe to take analogous observations; and although photography has not by any means been eminently successful in the duty it was called upon to perform, yet the process of Daguerre, as worked by the French astronomers, has, I understand, in point of result, given a higher degree of satisfaction than any other process selected either by our own or the representatives of any other nation.

The next advance in photographic science was by Mr. H. Fox Talbot for a process in which a negative picture was produced by means of a sheet of paper coated with a solution of iodide of silver, and afterwards immersed in a solution of gallic acid, nitrate of

silver, and acetic acid, the same solution also being used for developing the image after the sensitive film had undergone the requisite exposure. It was about this time that Sir John Herschel suggested the employment of glass as a support for the photographic film, and we all know with what tenacity that material still maintains its position as the one most suitable for the purpose.

The idea of employing an ethereal solution of pyroxylic as the basis of the photographic image was first propounded by M. Le Gray, of Paris, but it was left to Mr. Archer to carry out and improve on the idea which M. Le Gray had suggested. It was in the year 1851 that Mr. Archer published a description of his collodion process—a process which, as you are aware, has given a greater impetus and a higher degree of importance to the art of photography than any other element introduced into the science from that year to the present time.

It was about this period that the original Liverpool Photographic Society came into existence, and although many members of that Society have been removed from our midst, yet it gives me great pleasure to add that there are three or four members of the old Society who still take an interest in our proceedings, and who, I am glad to state, are likewise members of this Association. Permit me to mention the names of Mr. Forrest, Mr. Wilson, and Mr. A. Cook, all of whom have done good and honourable work in the past. The original society worked hard to unravel the mysteries of the nitrate bath, and without doubt assisted equally with any other society in this country to overcome the difficulties and intricacies of the various dry processes of those days.

The next important movement in the photographic art was one in which this Association holds a most prominent and honourable position—a position which cannot be disputed or divided with any other society. I mean the introduction of the bromide emulsion process—a process which is, without doubt, destined to exercise a most important influence on the future of the photographic art. The emulsion process was, as you are all aware, discovered and introduced by Messrs. Sayce and Bolton, the former of whom is still a member of this Association, whilst the latter has recently been appointed to the important position of Editor-in-Chief of "The British Journal of Photography," a publication which likewise owes its origin to our parent Society, and which, under the able management of its late esteemed Editor-in-Chief, Mr. J. T. Taylor, has done much to popularize and forward the progress of the art of photography. I am sure, gentlemen, we all regret the severance of Mr. Taylor's connection with "The British Journal of Photography," as during the interval of his association with that publication, extending over a period of fifteen years, he has done much not only to raise the character of the Journal in its literary capacity, but to impart to its numerous readers, by his clear exposition and great knowledge of photographic chemistry, a vast amount of useful information. As the founders of the journal in question, I am sure this Association wishes Mr. Taylor every success in his new home on the other side of the Atlantic.

Reverting to the question of processes; gelatine was the next progressive step, which for rapidity of action is certainly without a rival. Our excellent ex-President, the Rev. H. J. Palmer, is one of the principal workers in that direction. With a wonderful amount of energy combined with hard work, which only those who work can properly appreciate, Mr. Palmer has persevered with this process from the date of its advent to the present time. He has induced others, both here and in other parts of the kingdom, to lend a helping hand, and by the united efforts of Messrs. Kennett, Bennett, Swan, and Palmer, this process has been brought to a state of comparative perfection. Mr. Palmer individually has been the means of introducing several novelties, and I doubt not his name, as it deserves to be, will always more or less be associated with the gelatine process. Many professional photographers in this town, and also in London, are now adapting this process to the ordinary requirements of studio work, and therefore it would seem probable that a dry process may, after all, ultimately succeed in supplanting a method of manipulation which until now has maintained its position undisturbed during a period of twenty-eight years.

The introduction of a mechanical element, having for its object the equalisation of bromide of silver in an emulsion, is exclusively due to Mr. W. B. Bolton. It seems probable that a washed emulsion, when the principle of preparation is better understood, will become the process of the future. At present a sensitive plate prepared by this process is not always so reliable as could be wished, being at times defective in sensitiveness, or otherwise

iable to spots of a form from which the old emulsion treated with a preservative was to a great extent free.

Many different processes have been worked by the members of this Association during the past season; and, while I have seen some good pictures produced by Mr. Palmer with his favourite gelatine process, and likewise excellent productions by Mr. Potter with a washed emulsion process, I must confess, that individually, I have used for slow work—such, for instance, as landscapes—the old collodio-albumen process, as by its aid I find it possible to obtain a negative on every plate exposed, and, as a rule, a higher class of picture than can be obtained by any other dry process. I have a decided preference for quality above every other consideration, and I verily believe—taking into account the number of spoiled plates which invariably result from the use of any other dry process, nearly every one of which latter I believe I have tried—that I am able to obtain an equal number of good negatives from half the number of collodio-albumen plates. This process has one great advantage which I think is not generally known, viz., an exposed plate being to some extent self-developing, by immersing it for a few hours or (say), over-night in a solution of pyrogallic acid and water of the strength of two grains of the former to one ounce of the latter. Next morning you will be in possession of a soft negative full of beautiful gradation—a quality very difficult of attainment except by this or the wet process.

It is not, however, my intention, neither is it my desire, to depreciate the emulsion process. I continually make plates by that method, and, in fact, it is my intention to use plates which I have expressly prepared by that process in the demonstration of micro-photography, which it would have been my duty to have given this evening, but which, unfortunately, I have been compelled to postpone until a future meeting. At the same time I cannot conceal from myself the important fact—speaking from personal experience in the manufacture of dry plates—that a more perfect film and greater reliability can be obtained from a plate sensitised in a bath than one made by means of emulsion. The fault—if fault there be—is no doubt to a great extent mechanical, as it is well known amongst emulsion workers that there is generally a difference, more or less marked, in the character or behaviour of nearly every batch of emulsion which is made, notwithstanding the fact that an identically similar formula may have been adhered to on every occasion. It seems, however, probable that in future sensitised emulsion will be prepared commercially on a large scale, and probably by that means we may hope to obtain a greater degree of reliability, and more uniformity in the character of dry plates prepared by emulsion than has hitherto been the case.

In my experience of commercially-prepared emulsion plates during the past two seasons I consider there is room for very great improvement. It may have been my misfortune, but certainly during the past summer I met with the greatest disappointment and annoyance from certain commercial emulsion plates which formerly could have been relied upon for excellence and certainty of result. It is doubtful, after all, if there be a better formula for emulsion than one of the original formulæ of Mr. Sayce, which was—

Bromide of cadmium	6 grains
Bromide of ammonium	2 "
Pyroxyline...	6 "
Ether...	$\frac{1}{2}$ ounce
Alcohol	$\frac{1}{2}$ "
Nitrate of silver	12 grains

with a preservative introduced—or at all events used—by Mr. Phipps, which was composed of tannin, gum, gallic acid, and a trace of albumen.

Turning to other matters indirectly connected with photography, it is probable that the electric light will, in course of time, be much used as a source of illumination in the production of photographic work. It has been found possible during the past year to utilise it for portraiture, and I now hold in my hands two cartes, lent to me by the President of the Manchester Photographic Society, which were printed from a negative by means of the electric light. One negative was held a distance of twelve inches from the source of illumination during an interval of fifteen minutes, while the other was held a distance of twenty-four inches, the time of exposure in this instance having been thirty minutes. The negatives were indiscriminately selected from the stock of a professional photographer in a neighbouring town for the purpose of this experiment. It will be observed the prints are fully exposed, and in every sense undoubtedly illustrate the capabilities and one of the important uses to which the electric light may in the future be successfully applied.

Surely photographers—and especially amateur photographers—are about to enter on their long-wished-for El Dorado at last. In the past rapidity was at one time the great desideratum. Afterwards came a desire for quality, and lastly, an emulsion which would keep indefinitely. These desiderata have now been obtained, for gelatine, collodio-albumen, and washed emulsion fulfil all these requirements.

Is it possible, therefore, except in matters of detail, that any further improvement can be obtained in photographic processes? Perhaps in apparatus some further advance may be made, although several decided improvements have been introduced during the past two years. The question of glass remains just as it was twenty years ago. Is it possible to find a substitute? Mr. Palmer is our "fast man." "Gelatine" is his motto. He says there is nothing like gelatine. It is not only the best vehicle for the sensitive salts of silver, but it is likewise capable of acting as a light and portable support for the photographic film. He says glass is an intolerable nuisance, as when it falls it breaks, and is at all times excessive heavy in weight, which fact he particularly found to be the case when he ascended the Alps a year or two ago. Therefore Mr. Palmer says—"Try gelatine with a touch of ox-gall, and you will be a happy man."

However, gentlemen, in the best regulated societies there is always a difference of opinion. Our excellent original member, Mr. Forrest, on the other hand, totally disagrees with Mr. Palmer. A support such as that recommended is not sufficiently transparent for him. He concurs in the opinion of Sir John Herschel—that there is nothing like glass. However, time will tell, and I hope that he and Mr. Palmer will settle the question between themselves, and perhaps at our next annual meeting we may have some addition light thrown on what to photographers is really a very important subject—glass or gelatine.

PORTRAITURE BY ARTIFICIAL LIGHT FOR AMATEURS.

BY REV. H. J. PALMER.*

FOREMOST among the seemingly utopian photographic ideas which have from time to time occurred to me, there has always been that which I propose to bring before you this evening, namely, the possibility of taking successful portraits by artificial light without the necessity of incurring expenditure and difficulties beyond the ordinary wont of amateurs; and I think that the need of a method providing the means of accomplishing portraiture by night is one which presses more heavily upon us than upon professional photographers. In the first place, there are but few of us who are able to afford the luxury of a properly-constructed studio, in which the portraits of friends may be achieved with artistic management of the light; and, in the next place, it is at night mainly, when the various avocations of the day are over, both that we ourselves have leisure to pursue our photographic practice, and also that our friends are able to submit themselves to our manipulations.

At the beginning of last Christmas vacation I set to work to see if this desideratum was in any sense obtainable for myself; and the result of my holiday photographic employment has been so encouraging and successful that I feel warranted in bringing the subject forward to-night as matter which, whether in discussion or in a practical demonstration, may be of general interest.

I will not cuter into the subject of other researches and experiments in this direction, since I see that this has been done ably in the last number of the *British Journal*. I propose briefly to describe the simple apparatus which, after many failures and much experimentalising, I have adopted, and I do so in the hope that other workers may be able to effect improvements and satisfactory modifications of the method I propose to lay before you this evening.

My early efforts were made with magnesium wire, but I found it impracticable to use this without the somewhat expensive assistance of clockwork machinery. Phosphorus ignited upon saltpetre gives an exceeding bright and actinic light; it is, however, such an exceedingly hazardous proceeding to use it in any way that I speedily gave up

* Read before the Liverpool Amateur Photographic Association.

experimentalising with it. Messrs. Broek, the pyrotechnists, have prepared a compound of equal excellence as regards activity, but possessing the advantage of being entirely free from dangerous properties. With the light from this compound directed upon the sitter through the condensers of a lantern, I ascertained that I could obtain a good negative with the full aperture of a carte lens, and upon a Swan dry plate, in thirty seconds. The condensers of the lantern for this experiment were placed at the distance of a yard and a-half from the sitter. I found that, when desirable, half-tone was easily obtained upon one side of the face by, in the first place, widening the angle between the direction of the rays from the lantern and the axis of the lens; and then, by burning on the opposite side of the sitter, at a greater distance from him, but at a corresponding angle, a quantity of the compound about half of that burnt in the lantern; the result of this arrangement was successful, but not, however, conducive to the comfort of the sitter, and I therefore constructed the lantern which I have here, in which the light is softened and diffused through a linen medium.

This apparatus answers sufficiently well, and it has the merit of exceeding simplicity and inexpensiveness. I may describe it best as a diagonal section of a large but light packing-case, with a circular aperture at the top six inches in diameter. There is a row of small holes along the bottom of the two sides; a little door in one of the sides; and the front filled in with a light framework of lath, over which I have stretched a sheet of linen. The opening at the top gives egress to the products of combustion, those at the bottom are for the supply of air to the flame, and the door at the side is for the ready ignition

of the pyrotechnic compound. The stand for burning the latter is a light column of wood, on the top of which I have nailed a piece of tin. Thus the fire is raised to a central position in the lantern. The dimensions of the two triangular pieces at the top and bottom are thirty-six inches on the longer side, and twenty-two inches each on the other two. The height of the box is thirty inches.

The light power might be considerably increased by the use of reflectors; but this I have not found necessary, and therefore have not employed them.

The best position for the lantern is about $4\frac{1}{2}$ feet from the floor, at the distance of $1\frac{1}{2}$ yard from the sitter. This arrangement may, of course, be modified according to the greater or less sensitiveness of the plate employed.

I have not seen the Moule lamp, and know nothing of its construction. I do not think, however, that there is in this apparatus of mine an infringement of any patent rights.

My plan for getting rid of the smoke evolved is simple in the extreme, and, as you will see presently, is efficient enough, provided the chamber is sufficiently capacious.

I have here a number of common hand-boxes, from some of which the bottoms and tops have been removed, and the whole are pasted together so as to form a chamber of the lightest possible material. An aperture at the bottom corresponds in size with that of the opening at the top of the lantern; and, on being placed in position, this chamber suffices to hold the smoke evolved by one of the lights.

When the portrait has been taken the hand-box is inverted at the fireplace or in the open air, and the contents at once pass off.

The actinic compound is sent down by Mr. Broek in any quantities at eightpence per pound; but I have suggested to him that it would be a great advantage to photographers if he will supply the light ready made up in packets to burn from thirty to forty-five seconds. Meanwhile, I make my own packets as follows:—A sheet of brown paper is cut up into strips two inches wide, and these are pasted with ordinary paste. A common wooden roller, two inches in diameter, is past over the strips, winding each into a small ease. After pasting on a bottom of paper the tube is filled with the compound, and the latter rammed down. The top is now closed with thin paper, and the light is ready to be placed in position and “fired off” upon a sitter.

I have extemporised a background for these portraits by using the white back of a large map upon a roller, the surface being curved evenly into the shape of an alcove; but I believe that equally good results may be obtained without the employment of a background at all. I place the lantern at a distance of a yard and a half from the sitter, with the lens and camera in close proximity to the apparatus. The focussing is readily done by gaslight, and when it has been accomplished the slide with a Swan plate is placed in position, the shutter drawn up, and the cap removed.

The pyrotechnic compound is now ignited, and an exposure of from forty to sixty seconds is given. I cannot give any advice as to the position of the sitter, because I am not an experienced portraitist. It will be obvious, however, that the eyes of the “victim” should be directed towards the shaded portion of the room, and not towards the lantern.

We will now proceed to put the apparatus to the test, and I hope that the result, when the negative has been produced and developed, will prove in some sort a justification for my temerity in bringing this subject under your notice this evening.

PHOTOGRAPHY AT THE BANK OF FRANCE.

THE Bank of France would appear to have hit upon an ingenious method of treating doubtful customers. The establishment has for some time past availed itself of photography, and among its officers is a photographic detective, to examine suspicious documents though the medium of a camera, which under some circumstances exercises a sharper vision than the human eye. Where an erasure has been made, for instance, the camera detects it at once, let the spot be ever so smoothly rubbed over, while a word or figure, that to the eye has been perfectly scratched out, is clearly reproduced in a photograph of the document.

If we are to believe a recent account, the Bank of France has now added to its precautions an invisible studio placed in a gallery behind the cashiers. Hidden behind some heavy curtains is a camera, ready for work, and at a signal from any of the cashiers, the photographer proceeds to do his duty by depicting the particular customer who may be standing at the desk. The clerk engages the man's attention, and in a few moments the portrait is taken, and the Bank in possession of a photograph which may hereafter prove of value. The camera is then fitted with a fresh sensitive plate, and stands ready for use upon another emergency. How far such an arrangement could be of practical value remains to be seen, but the principal banking establishment in Paris has certainly to thank photography for the discovery of several frauds of late.

A photographic laboratory and requisites form part of the institution, and most of the officials themselves have to submit to the process of being photographed, so that the direction may be in possession of their portraits. This practice, it is held, is a deterrent against evil ways, for should any of the clerks be tempted to go astray they know very well that they leave records of themselves behind.

The same system prevails among the Paris Police, where every one, from the highest to the lowest, is photographed. The Paris Police, indeed, employ photography to a very great extent nowadays for the detection of crimes, and a large photographic establishment is to be found at their headquarters.—*Daily News*.

FINE ART COPYRIGHT.

THE question of fine art copyright still continues to occupy a large share of attention in the daily press, long letters and leaders appearing in various journals. The *Times*, returning to the subject, fails to see that the balance of argument is on the side of the artist. If, on the sale of a painting, the copyright must accrue silently to one of the parties in the bargain, unless stipulation in regard to it be made, the *Times* thinks the purchaser should have the advantage. The painter is more likely of the two, it is urged, to know the value of the intangible property attaching to the picture, and to raise the question of retaining it or receiving its specific value, than the purchaser, who is not unlikely to be in a state of dove-like simplicity and innocence, never dreaming of acquiring or losing anything but the painting itself. As professional picture-dealers form the larger class of purchasers direct of the painter, common experience will, of course, confirm the estimate the *Times* forms of their innocence and simplicity in making bargains! The stroug argument of the *Times* for the copyright passing with the picture itself is based upon the *prima facie* inconvenience of separating the actual possession of a picture from the intangible and incidental value of the copyright or right to multiply copies of it. But this surely should create no serious difficulty. Analogous cases are not wanting. A farm is let, whilst the right of shooting game over it is reserved. Land is sold, whilst the right of working minerals which may be found underneath it is reserved. But if this form of argument be of any value, it is essentially useful to the photographer, even if it militate against the painter. We admit that in relation to photography it would be difficult to separate the copyright from the negative, and the possession of the negative would naturally, in the absence of stipulation of any kind, give possession of the copyright therein. In fact, although the Royal Commission recommends that in portraiture the copyright shall belong to the sitter, or to the person commissioning or ordering the portrait, a memorial presented to the Government by the Royal Academy seems to be written under the impression that the copyright always accrues to the photographer. The memorial in question, setting forth a hardship of the painter's case, says:—

"The traditional idea of giving to the author or artist copyright in his works is embodied in the report in all that affects literature, dramatic literature, and music.

"In sculpture the Royal Commissioners recommend that sculptors shall have the fullest rights extending not only to

portraits, but to copies from ancient or other statues, and over photographs and drawings done from the sculptor's works.

"And in photography, that the copyright should be given to the photographer (he being by custom the proprietor of the negative). The ownership and the profits that accrue therefrom to remain with him in all cases; but when the photograph is taken on commission, copies are not to be sold without the sanction of the person who ordered it."

Whilst, it is pleaded, in regard to painting, there is to be a complete reversal. If, as regards photography, the provision is to be as stated by the memorial, photographers will have little of which to complain, and it may be prudent to put aside anxiety on the subject, at least, until the Bill is drafted, and the provisions of the intended law somewhat definitely formulated.

A REVOLUTION IN THE STUDIO.

WE invite the earnest attention of every photographic portraitist to Mr. Hazard's paper read before the South London Photographic Society, printed on another page. It describes a very definite step in the revolution in work in the studio which we have more than once expressed a conviction must inevitably soon take place. For the past three months, as a portraitist, Mr. Hazard has not used the negative bath in his business. How many more may have had the courage to make a similar experiment we do not know—probably many—but this is the first record of the entire abandonment of the negative bath. Very many able portraitists have been trying extra sensitive dry plates in studio work, and without a single exception, so far as the record reaches us, with complete success. One and all of many who have communicated their experience, have been surprised and delighted with the results. The rapidity has been marvellous, and the results charming.

It is natural, however, that the change should be made somewhat slowly. The skilled photographer who has mastered the wet process, which is worked in his hands with an even average degree of success, which satisfies him, is not anxious to change. Whatever may be the faults of the wet process, "it is," he exclaims, "good enough," and change always involves trouble. Old portraitists, who five-and-twenty years ago worked the Daguerreotype process, saw, with great dismay, that beautiful process superseded by the introduction of collodion. The Daguerreotype process was a dry process. It required very precise conditions; but, when these were duly secured, it gave great certainty of result. It was comparatively clean, and free from the "sloppiness," "mess," and uncertainty of wet collodion. But the change was not one of choice: it was inevitable. A new method must be acquired, or business must be given up, and there were some who preferred the latter alternative. No imperative pressure will, however, compel the portraitist to adopt dry plates in his studio in place of wet collodion. He who persistently adheres to the latter, however, will be placed in an inferior position when compared with his more advanced fellow practitioner, who, working with more sensitive plates, will excel in securing expression, taking babies, and in pleasing the public generally. No time being wasted in preparing plates, the sitter is detained a shorter time, and the sitting of twenty seconds being reduced to two, there is absolutely no time for moving. Waste by boiling down and otherwise doctoring baths will be abolished. The headaches and weariness arising from breathing ether and other villainous fumes of the dark-room will be abolished. In fact, an advantage is gained in every step which admits of comparison, and no loss of any kind that we can see. In place of the multitude of operating troubles of the photographer, there now awaits him, as Mr. Hazard has experienced, "calmness, peace, and joy"! We hail such a revolution for our readers with gladness.

LIGHT, AND ITS WORK IN ABSORPTION.

BY CAPT. W. DE W. ABNEY, R.E., F.R.S.*

I HAVE selected a very large subject on which I am to address you to-night; but I may say that I did it purposely, as it left me the choice of attacking any particular point that I might desire. I asked whether I might give you a scientific discourse, or whether I must confine myself to a popular explanation of some phenomena; and in a letter in reply to my query, the latter course was suggested, since it was stated that *at present* my audience was not advanced enough to take in anything beyond popular exposition. To those, then, who expect something startling or novel to be set before them, I must at once say, to-night you will not have it. I shall be elementary; in fact, so elementary, that I hope I shall be in the comprehension of all, or, at all events, of the majority. Now confession is good for the soul, so I must unburden myself to commence with, and tell you that I am guilty of calling my subject by the wrong name, though I daresay at first you will not perceive my mistake. Had I called it radiation and its work, I should have been nearer the mark scientifically, as you will perceive as I go on.

What is light, and what work does it perform? Light is a sensation, nothing else; it is the sensation of *radiation*, and the sensation is caused by a chemical process taking place within the eye. Now, you may say, you are explaining a fact which we all know well, by telling us it is something else. What is a radiation? Let me take you in imagination to the sea shore, and when there let us imagine we have a heavy swell running in towards the shore from the horizon, and that anchored a short way out is a boat with a load of men in her. The swell comes in, and the boat tosses about, rising and falling, it may be, five or six feet. If you had that boat with its load on shore, and tried to raise her five or six feet, you would find that you would have hard work to accomplish your object, which the water can do with ease. In other words, if you did raise it, you would really be performing the absolute mathematical *work* which the wave can do. The enquiring mind will at once ask, how it is that the waves can do with so much ease, what you can do with difficulty? Whence comes the capacity for doing it? Probably if we traced the swell to its origin we should find that a gale had been blowing over the water, and first one puff had caused a small ripple, than another, which made the first grow bigger, and so on, till we had large grand waves formed coursing after one another towards the point at which we were standing. We all know that the wind can press hard against us, and cause us to do work, or exert force to resist it; and in reality it is the energy of the wind in the distant sea which is conveyed by the wave's motion to lift the boats.

If we traced the matter still further, we should find that the wind was really transforming a part of the energy existing in the sun to the water, and that the prime cause of the work performed in lifting the boat was the sun. However, another point requiring attention is, that the portions of the waves which do the work are diminished in height, and a boat immediately between us and the one in question would not be nearly so much tossed about. Now, we will transport ourselves back to this lecture theatre, and apply the lesson learnt. But we must exercise our imagination a little further. Imagine ourselves (as we are) in the depths of an infinitely deep ocean of a something which is infinitely more elastic, that is more pliant, than our air, which can carry waves from the sun and stars to ourselves—and imagine, instead of the wind blowing on the sea to create the waves, that we have some small particle which vibrates rhythmically in one of these distant bodies. Then, since the ocean in which we are is infinitely pliant, the motions of that vibrating

particle will generate waves in it, spreading out in all directions, and travelling onwards till they reach us and pass us by.

Perhaps a diagram, which I can throw upon the screen, may be of use in showing you what I mean by wave-motion. Here we have, in fig I., a set of particles in a

straight line. When the apparatus is slightly turned, we have the particles arranged as in fig II., and oscillating backwards and forwards give the appearance of a series of waves, each one following its predecessor at an uniform rate. It will be noticed that the particles themselves never move forwards, but only across the direction of wave motion. These small waves then carry to us the energy that exists in the vibrating particle, far distant, and if we can stop the motion of the wave by any means—that is, annihilate it—it will be capable of doing similar work, which particle itself could execute, since, unlike the wind on the water, which is not perfectly pliant, it expends nothing in setting our ocean in motion. Well, how can motion be stopt? Waves of certain lengths can be stopt by the retinae of our eyes. There the wave meets with an opposition, and the work of the particle vibrating in the sun or star is transferred for execution in the eye.

And here let me say, that the work it does is that it chemically alters the constituents of a tissue which lies in the eye, and the fact of this alteration taking place gives us the sensation of light. The waves which emanate from the vibrating particle are called radiations, and evidently these radiations are carriers of possible work. Now in this medium *waves of any length between certain limits* can be generated, and it is quite possible, and is often the case, that all of them may be generated by a vibrating particle, and that, consequently, those wave lengths are present which give us the sensation of light. We shall see presently that the sensation of white light is in reality the sensation caused by a combination of wave lengths, which individually give the sensation of colour. We can now strictly define what light is. It is an exhibition of work, or the effect of work done, on certain matter which exists in the tissues of the eye. Take away from a man or alter in composition this matter, and we should say he is blind, that is, he has no sensation of radiation as light.

(To be continued.)

BEECHEY DRY PLATES.

BY A. A. MANTELL, M.D.

In the YEAR-BOOK for 1879 I observed that "Photo-Chemicus" has alluded to my remarks regarding Canon Beechey's emulsion process which I made in the YEAR-BOOK for 1878.

When using the preservative recommended by Canon Beechey I invariably employed a substratum without any blistering of the film, and it was only when experimenting with the gum-gallic preservative that this annoyance was experienced. My meaning was not expressed with sufficient clearness, although the adverb "however" would appear to qualify the sentence. I am sorry "Photo-Chemicus" cannot give a more favourable report of his further trials with the emulsion, for I consider his being unable to secure more than three perfect plates out

* Lecture delivered at Cheddle, Cheshire, at the Literary Institute, 24th January, 1879.

of four coated unsatisfactory. Supposing in a photographic tour every fourth, and consequently imperfect plate, was exposed on a subject most desirable to secure, what annoyance would accrue to the photographer on returning home, perhaps from a long journey, to find that he had failed in the very pictures upon which he had set his heart! "Photo-Chemicus" particularly draws attention to the importance of adding the silver nitrate very gradually, whereas Canon Beechey, in an article published in the "British Journal Photographic Almanac" for the current year, recommends preferentially the pouring of the solution in one thin but continuous stream into the collodion.

My experience accords with Mr. R. Gordon's, that the first few plates coated may be free from spots; they then appear, and it is impossible to get a plate free from them without re-filtering the emulsion, and even then I have seldom succeeded. I called at Messrs. Rouch's establishment last spring, and asked to see any specimen prints from their Beechey plates. A few were shown, but I must say I was disappointed in them.

Should I be asking too much of "Photo-Chemicus" to send me a good specimen print from one of his own Beechey plates to look at? I would return it without delay. By this means I should be enabled to form far better opinion of the value of the process than by reading any number of articles on the subject.

Honiton, Devonshire.

GELATINE PLATES IN THE STUDIO.

BY J. S. HAZARD.*

Nor having used the negative bath in my business for the past three months—having done all my work with gelatine plates—I have had many conversations with photographers on the subject. Some I find quite prejudiced against the process; others indifferent; whilst many are anxious to know what may be done. Inquiries from the last of those have induced me to read this plain, matter-of-fact paper on the subject; and I trust it will be so plain that beginners with dry plates will be encouraged to persevere, and that operators will be induced to acquire a knowledge of the process, and to keep in practice, as one of the questions to be asked in the future when a situation is applied for—"Can you work the gelatine plates?"

My first experience with these plates occurred in the first week of November last. After trying a few plates, and succeeding in producing negatives which I knew would have been impossible with wet plates, I was so convinced there was something good in the process that I at once built a special dark-room for their use, finding that my ordinary dark-room let in too much light.

Unfortunately, I have not had time to test all the plates in the market, but have postponed until better days the few experiments for which a professional photographer can find time. One kind—those of Wratten and Wainwright—were favourably recommended to me. These have proved all they professed to be, and I have got all I wanted from them in the studio.

I use the plates in the following manner: Having with care examined the dark slide, camera, and dark-room, to be certain they are light-tight—and upon this point I cannot speak too strongly, as many failures arise from its neglect—I come to the sitter. Here I find I must be sure there is plenty of contrast represented in the coming picture—in fact, must light rather harshly, as in development the shadows are apt to be destroyed, the plates having such a tendency to produce detail, and hence arises a danger of flatness. The exposure has been reduced one-eighth or one-tenth of the ordinary time for wet plates, some negatives, exhibited to-night, having been taken in one or two seconds during the dull, foggy days of last month.

To develop: I place the negative in an ebonite tray,

* Read before the South London Photographic Society.

covering it well with tap water. I let it remain there whilst the developer is being prepared (in my practice I always use plenty of solution—quite enough to cover the negative, as I find the atmosphere causes a scum on the solution which is apt to stain the film); hence for half plates I always use two ounces of water with six grains of pyro., to which are added three drops of—

Liquor ammonia	1 ounce
Water	1 "

pouring the water out of the tray. The plate is covered with this for a few seconds; then are added as many drops as may be deemed necessary of—

Bromide of ammonia	80 grains
Liquor ammonia	1 ounce
Water	2 ounces

As a rule, when I think sufficient exposure has been given, I use sixty drops of this; if a short exposure—say through a child having moved—I use one hundred drops. To show what may be done by modifying the developer I produce two negatives—marked "H" and "S" ("hard" and "soft")—of the same person, each having received precisely the same exposure. The negative marked "H" was developed by the formula mentioned; that marked "S" by three grains of pyro less in the developer. The development must proceed until all the detail is out. If it "hang fire," a few drops of the water and ammonia solution will hasten it. It ought to take very little more time than a wet plate. When developed, the negative is well washed, and then fixed in hypo, cyanide destroying the intensity very quickly. The fixing must be prolonged after the negative appears to be fixed, or stains will manifest themselves when the negative is dry. After washing thoroughly it must be allowed to dry spontaneously in a place free from dust.

Should it now appear to be not quite intense enough, it may be strengthened by silver and iron. In practice, however, this is seldom required.

When varnished the negative will be found to require much less retouching than a wet plate, being full of rich detail and delicacy; and, although taking somewhat longer to print, it will produce results quite equal to the "doomed" wet plate.

I claim, then, for the gelatine plates the following good qualities:—Their extreme sensitiveness—hence their adaptability for portraits of children and invalids at home, and also for catching better expressions in portraiture; their quick and easy development; their freedom from granulation (for the deposit is a mere stain), and thus for enlargements we get much richer results. They abolish from the studio that old abomination, the head-rest, also the smell of collodion—a great annoyance to customers. In the dark room ether, alcohol, glacial acetic acid, and cyanide of potassium must cease to wage war against the photographer's health. On busy days they will prove a blessing; for, not only being always ready for the sitter "who cannot wait a minute," they can also be exposed and the development postponed until the close of the day. No more split films, or saying "good-bye" to them as they slip down the drain-pipe! No more dirty fingers, as the negatives need never be touched until they are washed! No more boiling or testing of baths, or spilling of silver solution; but calmness, peace, and joy in the use of gelatine dry plates!

NOTES ON THE PLATINOTYPE PROCESS.

BY W. WILLIS, JUN.*

THE principles upon which the platinotype process is founded have been so frequently published that I will not occupy your attention by any restatement of them.

In the old or first-described process it was found necessary, in order to get an image which would adhere to the paper, and which would be free from granulation, to introduce a salt of silver. This introduction of silver necessitated the use of hyposulphite of soda. Now you all know that silver

and hypo. bear a bad name, and the use of them in the process gave it a blot which I was anxious to remove. After some laborious experimenting I discovered a method by which both of these objectionable ingredients could be dispensed with, and purer results obtained, in a wonderfully simple manner, by the use of only one reducible metal—platinum or iridium.

The new process may be described in a general way as follows:—Paper is coated with a mixture of platinum and iron salts, and then dried. It is now exposed under a negative; after exposure it is floated for a few seconds on a hot solution containing oxalate of potash and a salt of platinum. This solution develops the print, which has then merely to be washed in a weak solution of acid to remove the iron salt from the paper.

I will now proceed to give a detailed account of the manner in which the process is actually performed.

The chemicals made use of are the following:—

A solution of ferric oxalate containing about 120 grains of the salt in each ounce. This is the iron solution.

A solution containing thirty to forty grains of potassic chloro-platinate, and three to four grains of plumbic chloride. This is the platinum solution.

A solution containing in each fluid ounce 120 grains of potassic oxalate and seven grains of potassic chloro-platinate. This is the developing solution.

A sheet of suitably-sized paper is placed on a glass plate and held there by any convenient means. The sensitiser is made by mixing equal quantities of the before-described iron and platinum solutions; two drachms of this mixture are now placed on the paper, and spread evenly over it by means of a piece of flannel wound round a glass rod. The paper is then hung up to dry, and as soon as surface moisture has disappeared the drying is finished before a fire or stove. The sensitised paper is now ready for exposure under a negative, which is done in the usual manner. The right exposure may be determined by inspection or by an actinometer. I prefer the latter as being more simple. A sufficient quantity of the developing solution is then put into an enamelled iron dish, and heat is applied underneath until the solution has nearly reached the boiling point. The exposed prints are now floated on this hot solution for two or three seconds; the image, visible on the papers before they are thus floated on the developer, consisting of a sub-salt of iron, is dissolved by this solution, and in its place is left a picture in pure metallic platinum. When removed from the developer the prints are washed for a few minutes in a very weak solution of oxalic or citric acid, and are then finished by washing for half-an-hour in three changes of plain water.

In sensitiveness the process is about three times as rapid as silver. The sensitised papers and the exposed, but undeveloped, prints have been kept in a dry state for upwards of two months without any deterioration. They may probably be kept for a very much longer period.

You all know that platinum is one of the most permanent substances with which we are acquainted. The prints made in that metal by this process are, practically speaking, impregnable. I have not succeeded in injuring them by any reagent, save only hot *aqua regia*.

PHOTOGRAPHIC HEADS IN PAINTED GROUPS.

AN action, *RIDLEY v. TUCK*, which was heard in the Court of Exchequer, contains many points of interest to photographers:—

Mr. Murphy, Q.C., and Mr. R. Bray, were counsel for the plaintiff; Mr. Talfourd Salter, Q.C., and Mr. Phillips, appeared for the defendant.

This was a case of some interest to the artistic world. It is an action by an artist against a seller of photographs in Regent Street, to recover 150 guineas, the price of an autotype picture, to be painted by the plaintiff, of the Pan-Anglican Synod, containing portraits of at least eighty of the Bishops; the defence being that before any money was to be paid, a preliminary

sketch was to be done, and if this was approved by the defendant and Mr. M'Lean, of the Haymarket, then the order was to be confirmed. As this condition precedent had not been performed, no money had been earned.

After Mr. MURPHY had opened the plaintiff's case,

Mr. Ridley was called, and stated that he lived in Buckingham Palace Road, and had been an artist for twenty years; he had done a group of the Royal Family, which had appeared in the *Graphic*. The drawing was his, but the heads were filled in with photographs. The defendant wished him to execute a similar work for him, and the price was to be fifty guineas, half to be paid at the commencement of the picture, and half at its completion. He had finished this picture and had been paid in the summer of 1877 by two cheques of £25 and £20 from Mr. M'Lean. In September negotiations were opened for painting the Pan-Anglican Synod in the same way with the defendant, and the plaintiff, in a letter of the 11th of October, said his lowest price was 150 guineas. The defendant said he was to buy the photographs himself, and not to tell the price to Mr. M'Lean, as he would probably object to spending so much money. The drawing was commenced on the same terms as the Royal Family group in December, and in three weeks a group was prepared, which was shown in Court, about half finished in black and white, with some of the faces just sketched in. The plaintiff was then asked by Mr. Salter if he had not received a letter from the defendant saying a preliminary sketch was essential in October, but the plaintiff denied ever having received such a letter, though he had written to the defendant saying the work was ready for inspection. This, however, the defendant afterwards denied. In February (Mr. Ridley continued) I called on the defendant, and he asked me how the drawing was progressing. I asked him when could he come and see it? Why had he not done so before? The defendant seemed astonished, and said he thought I had given it up. I said, "No; have you not received my letter?" But he said he had not. After three weeks I called again, and again asked the defendant when he would come and see the picture. He said he and Mr. M'Lean had quarrelled, there had been a "brush" between them, and he dared not asked him to go just then, as he was so angry and irritable. But he, the defendant, was going to marry a rich young lady, and that would smooth Mr. M'Lean over and square matters with him. The defendant frequently said he would come to see the picture, but he never did. In March my solicitor wrote asking for the seventy-five guineas, and this action was commenced in April. One hundred and fifty guineas is a fair price for this picture; indeed, very little, as it is two-thirds finished.

Cross-examined.—The *Graphic* picture was the first in which I adopted the plan of filling in the heads with photographs.

Mr. SALTER.—Then you left vacant spaces for the heads that the resemblance might be the more striking?—Yes.

Cross-examination continued.—There was no preliminary approval of the sketch in the first picture. I received the first payment at the commencement of the work; they did not approve the sketch before I got a shilling. I received some pay when it was commenced; the design had not to be approved before the order was given. The design, however, had advanced to as far as this (the picture in dispute) before I received any money. The arrangement in the second was to be the same as the first case, and my first payment was as early as was agreed to. Both Mr. Tuck and Mr. M'Lean saw the picture, but they had nothing to do with approval, though they said they liked it. It was not a condition of payment that it was to be approved at that stage, though they had to see the work. Pressed by his Lordship, the witness said it was necessary that they should approve before I got my first payment. I had no order to proceed, but I went on with the work. I cannot say how much longer this picture would have taken to finish—two or three days, or longer; but it took three weeks' continual work to arrive at the present stage. The Royal Family group took a week to arrive at this point. I did not know the Bishops by appearance, except three or four, well enough to remember their features. I had to guess at the bodies, and then to suit the heads to them.

Mr. Justice HAWKINS.—Do you draw a lot of bodies of different sizes, big and little, and then stick a head on, and say that will do for him?

The Witness.—Just so, my Lord. You allow three heads for the size of the body, and you judge from the type of the head and shoulders. Mr. Tuck objected to the picture of the Royal

Family being so low, and to the straight line of heads in the background; but they did not alter the picture. I suggested the introduction of a dog into the picture, but that is addition, not alteration. It certainly was not a condition that they should approve. The order was given a few days after October 11. I began early in December, and I saw the defendant before February. He did not then say so many months had elapsed that he thought I had given it up. I said the picture was in an advanced state; he did not say I ought not to have advanced so far till he and Mr. M'Lean had approved it. I asked the defendant for a cheque, but M'Lean was finding the money. I could not do anything more than I did. The present picture is worth £100. The plaintiff's case, after a short re-examination, closed.

Mr. T. SALTER then opened the defence, and said the action was premature, as the agreement had not been performed. Mr. M'Lean had a good name to keep up, and would not pledge himself to accept a picture of the Pan-Anglican Bishops grouped in a way he knew nothing of, anyhow Mr. Ridley might choose. One person misplaced might make the whole thing ridiculous. It was a difficult matter to arrange the Bishops according to etiquette, putting the prominent ones in commanding positions, and the Colonials, he presumed, in the back rows.

Mr. Tuck was then called, and said he was an artistic photographer. It was a distinct understanding with the Royal Family picture that it was to be submitted to him and Mr. M'Lean before any money passed, and the Synod picture was to be on the same terms.

Cross-examined.—We had agreed to bring out the Pan-Anglican Synod if the sketch was satisfactory. The price was not definitely settled at 150 guineas, but no other sum was mentioned. The plaintiff said nothing about half payment on commencing.

Mr. M'Lean, a publisher of engravings in the Haymarket, was then called, and said he was not present when any bargain was made. He was much engaged, and certainly away from town between February and April, 1878.

Cross-examined.—The defendant asked me to go and see the work. I promised, but did not go. It is the invariable rule for artists to submit a preliminary sketch before receiving an order. Some artists might do this much work—i.e., the present picture—in two or three hours; others would take as many days or more. I did not think there was any particular occasion for going to the studio in February.

After hearing the counsel for the defence, the judge summed up, and the jury then said they found the plaintiff's version the correct one.

His LORDSHIP.—That will be a verdict for the plaintiff for seventy-five guineas. Cannot you come to some terms to complete the transaction? Here are the terms that seem just to me (handing down a piece of paper).

After a brief consultation,

Mr. MURPHY said his client agreed to take £95 and give up the picture.

His LORDSHIP.—That is very fair. These things, gentlemen, ought always to be reduced into writing. All this direct conflict has arisen out of this. I should be sorry to think that your verdict was based in any way on the supposition that either the plaintiff or the defendant had told an untruth.

Several jurors.—Oh no, my Lord, not in the least.

Correspondence.

SOLIDIFYING OF GLACIAL ACETIC ACID.

SIR,—As an amateur, I do not photograph in winter for lack of opportunity. I have a little dark room which serves me as photographic "parlour and kitchen and all;" it is glazed with ruby glass fitted in an inner frame. On a shelf, amongst other chemicals, stands a bottle of glacial acetic acid. During the late frost the thermometer was very rarely above 32°, as the little room is built out and very exposed; yet the glacial acetic acid remained quite fluid, and I thought something was wrong with it, as water placed in the room rapidly became a block of ice.

I had occasion to go in the room yesterday; thermometer

at 50° (acid fluid). I removed the ruby glass for repairs; after a short time again went to the room and found the acid solid. Is it known that the acid does not become solid in red light at the same temperature as it will in white? —Yours obediently,
E. P. P.

MUFFINS AND PHOTOGRAPHY.

DEAR SIR,—Your correspondent of last week has, I think, made a mistake as far as he is concerned. During the conversation I had with the man I met at St. Lawrence, he gave me a photograph, which I enclose, with description.

The letters upon the barrow were yellow, not black shaded with red; and the word "Ramsgate" was not upon the barrow, simply because the man did not belong to Ramsgate.

If the muffin photographer of last week is the same man that I saw and held conversation with, he will be able to give a faithful description of the photograph; and if he fails to do so, why then I shall expect him to stand a plate of good muffins well buttered for tea.—Truly yours,

41, Queen Street, Ramsgate.

A. J. JARMAN.

P.S.—Next week I wish to say a few words on a curious phenomenon in dry plate photography.

PHOTOGRAPHIC USE OF OXALATE OF IRON.

SIR,—As an old reader of the PHOTOGRAPHIC NEWS, I am well up in the history of photographic processes. I was somewhat disappointed, during the recent discussion as to the original use of oxalate of iron, to find no reference to a valuable piece of evidence. Just five years ago a letter from Sir John Herschel appeared in your pages making certain reclamations in regard to cyanotype processes, and in the following week's issue a letter appears from Dr. Phipson, in which he says: "The letter by Sir John Herschel in your last number gives me an opportunity of establishing in your weekly circulating columns my priority to the process of obtaining photographic proofs by means of oxalate of peroxide of iron. The learned physicist just named owns that in making his interesting researches upon the action of light on salts of iron he never employed the oxalate of iron." He then proceeds to give details of his own discovery, referring to the record of it in these pages which has recently been mentioned. Sir John made no reply to this letter, practically acquiescing in its claims, as, having written in the previous number, he was presumably in the habit of seeing your journal. I have referred to this correspondence as settling the question more satisfactorily than any amount of inference.—Yours respectfully,
LOOKER-ON.

[Sir John Herschel received the PHOTOGRAPHIC NEWS, regularly, and made frequent communications through its pages.—Ed.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE annual meeting of this Society was held on Tuesday evening the 11th inst., in the Water Colour Gallery, Pall Mall, Mr. JAS GLAISHER, F.R.S., in the chair.

The minutes of the previous meeting having been read and confirmed, two gentlemen, whose names we have not at present, were elected honorary members of the Society.

Messrs. W. S. Bird, R. C. Murray, and W. Cobb were appointed scrutineers of the voting papers for the officers for the ensuing year.

The Council's report was then read by Lieut. E. DARWIN, R.E., and a vote of thanks, proposed by Captain ABNEY and seconded by Mr. P. MAWDSLEY, passed to the Hon. Secretary for his services.

Mr. JOHN SPILLER, F.C.S., then read the Treasurer's Report, and entered into explanation of the Society's financial position, which was considered to be eminently satisfactory.

A vote of thanks was carried unanimously, on the proposition of Captain ABNEY, seconded by Mr. T. SEBASTIAN DAVIS, who spoke to the onerous character of the duties involved.

The PRESIDENT then called for a vote of thanks to the Auditors, which was, of course, carried, and, alluding to the Progress Medal of the Society, stated that its award was still under the consideration of the Council. He hoped that during the year sufficient progress would be made to enable them to make the award at the annual meeting. Referring to Captain Paget's prize, he stated that a committee of adjudication had been formed, and he hoped they would soon be in a position to make a report. He believed that the presentation prints would be, in the course of a few days, ready for distribution among the members.

A vote of thanks to the President was proposed by Col. STUART WORTLEY, seconded by Mr. W. BEDFORD, and duly passed.

Mr. GLAISHER responded. He believed that he was one of the oldest members of the Society, as, at King's College, Conduit Street, and in their present rooms, he had almost always been present at their meetings.

The following gentlemen were duly proposed and elected members of the Society:—Rev. Chas. E. Few, Messrs. Albert Grant, M. L. Tronp, and Hanwell Williams.

The Scrutineers having handed in their report, the following were declared elected to fill the places of the retiring officers:—

President.—Mr. James Glaisher, F.R.S.

Vice-President.—Mr. J. H. Dallmeyer.

Treasurer.—Mr. John Spiller, F.C.S.

Hon. Sec.—Lieut. C. Darwin, R.E.

Council.—Messrs. W. Bedford, L. Warnerke, G. Wharton Simpson, Prof. G. G. Stokes, Col. Stuart Wortley, Lieut. C. Darwin, and, to fill the place of Mr. J. H. Dallmeyer, elected vice-president, Mr. F. York.

A paper by Mr. John Harmer was read on "A New Camera for the Studio."

Capt. ABNEY, R.E., F.R.S., read a paper "On Gelatine Emulsions."

Mr. WILLIAM BEDFORD read a paper "On a New Instantaneous Shutter."

Mr. F. HENRY exhibited and explained a new arrangement obviating the necessity for hinging the shutter on the dark slide.

Discussions followed, and will be reported when we print the several communications.

Mr. J. TALBOT LANE exhibited and described a new arrangement for vignetting.

The PRESIDENT, in adjourning the meeting until the 11th of March, appealed to the members to bring forward whatever they might have of an interesting character to add to the pleasures of the monthly gathering, as the water-colour drawings now on the walls would then be removed.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on Thursday evening, February 6th, at the Society of Arts, John Street, Adelphi, the President, the Rev. F. F. STATHAM, M.A., in the chair.

The minutes of the last meeting were read by the Secretary, and confirmed.

The following gentlemen were then elected members of the Society:—Messrs. R. W. Statham, W. B. Bolton, W. York, A. L. Henderson, A. H. Chambers, and C. H. Dufaur.

The CHAIRMAN then called upon Mr. Hazard, who read a paper "On Gelatine Plates in the Studio" (see page 80).

At the finish of the paper the Chairman invited discussion.

Mr. P. MAWDSLEY said he fully agreed with all Mr. Hazard had said respecting the extreme sensitiveness and simplicity of development of gelatine plates, and considered they were a great boon to photographers during this dull season of the year. Mr. Hazard's specimens demonstrated the truth of his statements.

Mr. CUTCHEY acknowledged that the plates worked well during the cold weather, but how would the gelatine stand during the hot summer months? He had recently developed a good negative, and, being anxious to test the printing qualities, he had endeavoured to hasten its drying at the fire, but the result had been utter ruin to it. He had found on a previous occasion, when using a gelatine substratum, that the negatives cracked all over when varnished. He had at first attributed this to the employment of an old collodion, but upon changing that without removing the defect, he concluded it arose from the gelatine.

Mr. MAWDSLEY said that he had found the plates work very well if prepared with a good sample of gelatine, taking care to keep everything as cool as possible.

Mr. CUTCHEY said one difficulty was at the present season that the plates were so long in drying.

Mr. FOXLEE remarked that that could easily be overcome to a certain extent by flooding the plates with methylated spirit: they would then be found to dry much more rapidly.

Mr. F. YORK said that while in Paris last year, he had failed with many plates through over-exposing them. He found that out by having to cap the lens before he had given sufficient exposure, as he thought; but on developing it he found that in this instance the exposure was correct, and attributed his failures with the former plates, to developing them all with two thicknesses of ruby glass, and it was not well to get too near that; he also found that gelatine plates retained their sensitiveness in winter, whereas collodion plates were very insensitive, and he could not account for it.

Mr. F. HOWARD thought it better to develop gelatine plates in a white dish than a black one, as recommended by Mr. Hazard, as the detail could be more readily seen.

Mr. KENNETT remarked that it was now five years since gelatine plates had been introduced, and it seemed only at the present moment that photographers in general were aware of their high degree of sensitiveness and their usefulness in dull winter light. He had developed plates with the glass standing at 98° without the least difficulty, taking care to use the water as cold as possible. He cautioned all photographers, when preparing the plates or developing them, to be very particular about the kind of light they worked by, and to use as little as possible, and to thoroughly wash the plate between each operation to obtain brilliant results. If sufficient water was used, the plate would have a matt-like appearance.

Mr. COBB fully endorsed all that had been said about gelatine plates in the studio. It was now three months since he had used the bath, and had been successful with subjects with which at ordinary times, even with good light, he should have failed, and photographers now need not fear dull weather. He thought it very instructive to keep reference of failures when they occurred. He considered that most of the failures were caused by over-exposure.

Mr. F. A. BRIDGE said that he had found no difficulty in developing gelatine plates since he had covered his dark room window with an intense orange yellow paper (it could be had of most of the dealers). He varnished it with varnish which made it bright like tracing-paper.

Mr. HAZARD fully agreed with all that had been said in regard to failures by over-exposure. The time had fully arrived that an instantaneous shutter could be used in the studio with advantage.

Mr. W. WILLIS, jun., then read a paper on "The Platinum Process," and demonstrated it by developing a number of prints, which seemed to give great satisfaction by the rounds of applause which were given.

Mr. A. L. HENDERSON asked whether exposures could be made in the camera to produce a transparency, and, if so, what would be the exposure?

Mr. WILLIS replied that he had not the least doubt but what it could be done. He had not tried it himself, but a gentleman, Mr. Clements, of New York, was present, who, perhaps, could give the desired information.

Mr. CLEMENTS said that he had produced, he should think, five hundred large prints by exposures in the camera; he had given about twenty minutes. He had found the electric light very suitable, as platinum was very sensitive to this kind of artificial light. His size pictures ranged from 17 by 14 up to 70 by 45 inches; he also found they were very suitable for working up either in colour or chalks, more so than any other kind of prints that he knew of. A question was asked whether the cold tone could be overcome.

Mr. WILLIS said that he had been making some experiments in that direction, which he had not yet finished, and had been successful in altering the colour by the use of iridium salt.

A vote of thanks was then given to both the gentlemen for their valuable papers, and the meeting terminated.

Talk in the Studio.

THE ELECTIC LIGHT.—Mr. Swan delivered an excellent lecture on the electric light, at the Literary and Philosophical Institute, Newcastle-on-Tyne, one night last week, Sir William Armstrong in the chair. After sketching the history and pro-

gress of experiment with electric lighting, be expressed a conviction that gas would not be superseded, but that each mode of illumination would have its specific and valuable use.

MR. F. A. BRIDGE AT THE BRUNSWICK INSTITUTE.—The worthy treasurer of the South London Photographic Society is a favourite in South London in connection with other arts than photography. We find the following in the *South London Press*: "On Monday evening this deservedly-popular entertainer made his fifth appearance at the South-Western Institute, Vauxhall, in his new *monologue de circonstance*, entitled, "Paris Exhibition; or, My Trip with Gaze to Gaze on the Gay City." Mr. Bridge's ability, both as entertainer and vocalist, is so well known that it is almost needless to say the audience heartily applauded the anecdotes, and *bon mots*, and lively musical selections with which the entertainment is plentifully provided. We regret to learn that the energetic chairman of the Institute committee, Mr. Ellingham, has for some time been suffering from severe indisposition, and has been unable to perform his official duties in connection with the Lambeth Union."

STATE AID TO ART.—In the last number of the *Kunst-Chronik* a comparison is made between the art budgets of France and England for the present year, and it is shown that, although the French Government grants aid to a much larger number of art institutions, museums, public buildings, manufactures, &c., the total sum voted for the present year was less by about three million francs than that allowed by England, which only supports the South Kensington Museum, the British Museum, the National Gallery, Portrait Gallery, and the museums of Edinburgh and Dublin. This is noteworthy, for we are apt to think that the State aid granted to art in France is much larger than in England; and so it is, but it certainly, according to these budgets, does not cost so much. The *Kunst-Chronik* proposes to compare also the budgets of other countries, especially Germany and Austria.—*Academy*.

PHOTOGRAPHY OR PHILOSOPHY.—Her Shakespearian education had been neglected, but when she told him, "There are more things in heaven and earth than are dreamt of in your photography," she smiled proudly, as one who had said a good thing, and knew it.

To Correspondents.

W. K. J. complains that he cannot succeed with the mounting material described by our correspondent TRYWELL in our pages a short time ago. The dextrine in spirit and water, he says, make a creamy mixture, without any adhesiveness. We think it is probable that he has not applied sufficient heat. Other correspondents who have tried it speak highly of it.

R. JACKMAN.—We think No 1 in your list will suit you best.

LEO.—If you carefully follow out the instructions which have been repeatedly given in our pages for precipitating an old bath with carbonate of soda, and redissolving the carbonate of silver with nitric acid, you will obtain an excellent printing bath on adding water to make the proper strength. For such a purpose recrystallizing is not necessary. The method of proceeding to make a negative bath ought to give you good results.

TRANSFER.—There have been articles in our back volumes and in some of the YEAR-BOOKS containing instructions for transferring collodion films to canvas, but there is no work devoted to that subject. There are full instructions on p. 89 of our YEAR-BOOK for 1870 (which is, however, out of print), and also on p. 421 of our thirteenth volume (September 3rd, 1869). If you have no access to them, we may take occasion to reprint them when we can spare space. 2. Warm tones in collodion transfers are obtained by skill and experience, using a pyro developer, and full exposure with short development. Some operators add chloride to the collodion to obtain this effect. The use of Selle's intensifier also gives a warm tone.

HUGH WALKER.—You do not require any special lens for enlarging. The lens described in a catalogue as intended for a solar camera is probably a condenser, which would not be of any use to you. Your quarter plate lens will answer. With it, and your camera extending forty inches, you can probably enlarge to four times the original size. Do you understand how to proceed about the operation? If not, write again, and we will give you some hints.

NORTHERN NOTES.—The letter signed "The Advertiser," commenting on "Northern Notes" in our last, is inadmissible. If our correspondent wishes to correct any inaccuracy or misstatement in such "Northern Notes," we shall have pleasure in giving publicity to such correction; but we cannot devote our space to the personal criticisms of one correspondent upon the communications of another.

A. CARPENTER.—There are various methods whereby you may decrease the intensity of your negatives. If you give a little longer exposure and less development, you will effect it. If, in applying the developer, you send it over the plate with a sweep, driving part of the free nitrate on the plate away and off the edges of the plate, the negative will be thinner. But the print you enclose is not from a negative which is too intense; it is, on the contrary, just about right in that respect.

J. L. R. (Surgeon-General).—We regret that we are not acquainted with Mr. Willis' address, but will endeavour to ascertain it. So far as we know, he has no agent or commercial representative at present.

W. W.—You slightly misconceive our object in recommending pyro development in some cases. It is not with a view to the production of transparencies as aids to enlargement we have recommended pyro development, but in producing collodion prints for transfer to paper, in which the colour of the image by reflected light is of all importance. In producing transparencies to be used as such, the appearance by transmitted light is of chief importance. And even in producing transparencies as aids to enlargement, pyro development is often valuable as giving an image less granular or crystalline than iron development. The great superiority of iron in developing negatives is chiefly in the rapidity gained by its use, which is not a matter of importance where no sifter is concerned. 3. An alkali is the best solvent for dried albumen.

J. A. A.—A spark from a Leyden jar proved, in an experiment with a specially rapid process, sufficient to give an image of large printed letters; but whether it would be of any value in lighting a subject requiring modelling and detail, we do not know; but think it very doubtful.

R. L. G.—There is little doubt that the sketch was considerably exaggerated, as we suggested.

R. W. DUGDALE.—In using Kennett's dry plates, or those of any other commercial maker, you cannot do better than follow the instructions for developing and all manipulations precisely as they are given in the printed instructions.

B. L. F.—If you are using a collodion which shows a tendency to split on drying, a coating of gum, gelatine, ale, albumen, &c., applied whilst the film is wet, preserves it from splitting in drying. Albumen is the best of these, as being least hygroscopic.

C. E. W.—We are greatly obliged by your suggestion. The subject is one which has been well considered, and the conclusion is that it is not desirable, or possible, with advantage, to put it in operation at present.

D. G. WESTON.—There are various methods of producing slides for the lantern. Your own familiarity with processes will decide which is the best plan for you to adopt. If you work any dry process, use it for producing your transparencies. If you are only familiar with wet collodion, you may produce transparencies by its aid. We have no space in this column to describe in detail any process. You will find many articles in our pages and in our YEAR-BOOKS. On page 76 of the last YEAR-BOOK issued, you will find an interesting article on the subject. 2. The lens will do. A capital manual on the subject, by Mr. Chadwick, was recently published by Warno and Co.

THE LUXOGRAPH CONTROVERSY.—We feel bound to abide by our published intention of inserting no more letters continuing this discussion, although we have received a long letter from Mr. Faulkner, who appears to think that we have taken sides in this inconvenient and uncomfortable dispute. It is our rule to avoid taking sides in the discussions in our pages, and we have taken none, nor expressed in any way, so far as we remember, any opinion of any kind. As we are challenged on the subject, we may say that as regards the Luxograph itself, so far as we have had opportunity of examining it and seeing the work done, our opinion of it is favourable, and we shall have something more to say on the subject shortly. Regarding Mr. Faulkner's ground of offence, the publication of an alleged verbal expression of opinion as a testimonial, either for or against, there cannot, we think, be two opinions as to its impropriety. Publication of remarks made in conversation cannot be defended on any ground of good taste or fairness, and we have no doubt that a thing done in the impulse of business eagerness has been regretted, and an expression of such regret, when the "testimonial" was disclaimed, would have been the best termination of the error. An interesting announcement in Mr. Faulkner's letter is to the effect that he will shortly be able to describe an apparatus for artificial light for portraiture, which may be made very cheaply. He asks if any of our readers can give information as to the best pyrotechnic composition for producing an actinic light.

A. BROTHERS.—Many thanks. We shall have something to say shortly on the subject.

FRANCIS BEATTY.—Many thanks. Attention in an early number. Parcel received. Many thanks.

A. J. JARMAN.—Many thanks.

Several Correspondents in our next.

The Photographic News, February 21, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

GELATINE PLATES IN THE STUDIO—SIGNALS BY SUNSHINE—THE PHOTOGRAPHERS' BENEVOLENT ASSOCIATION AND ITS SUPPORTERS.

Gelatine Plates in the Studio.—It will be some time, doubtless, before dry gelatine plates are generally used in the studio, but from the favourable impression that they have made upon certain prominent photographers who have employed no other medium for months in their work, there can be little doubt about their ultimately taking the place of wet plates, and bringing about the abandonment of the dipping bath. It is this latter which is a constant source of worry to the young and unskilful. Its behaviour ever varies with the weather, while its acidity of temper is known to all. If you cannot rely upon your nitrate of silver, you cannot trust your dipping bath, and a dipping bath out of humour for the morning may destroy your day's work. Old photographers seldom agree in their way of treating their baths. Each acts according to his own experience and judgment. Some let the solution alone, some doctor it. Some believe that sunning and filtration are enough to work upon the most refractory of solutions, while with others the permanganate is an infallible remedy. Not a few do not bother themselves with a curing solution. They throw it down in the residue tub and make a fresh solution, or, if they do much silver printing, employ it in their paper bath. When it is cold the bath acts feebly; when it is hot, we get unequal patches over the plate; when it is neither hot nor cold we are liable to pinholes, fog, and streaks in the direction of the dip. "What causes markings like that in the bath?" beginners will ask you, showing you a stained plate. And by way of reply, you may frankly say, "A hundred and fifty things." There are so many points to be observed, that unless you make up the bath yourself and know all about its condition, you might guess twenty times before you get at the real source of error. You may be a very good judge of the defects and their cause in your own bath, but it is difficult to hit upon it in anybody else's, and for this and other reasons, photographers will not be sorry to part with their old enemy. There will be little regret in our studios if we have to part with the dipping bath; it gave us, perhaps, no extraordinary amount of trouble when we were used to it, we shall say, but it was a matter that required looking after and demanded our constant attention.

Signals by Sunshine.—They have been employing light as a means of signalling in the Khyber Pass, and instead of the electric telegraph, the light signals being flashed from one party to another by means of a heliostat. We believe the distance is but five or six miles between the stations, and the line appears to work with considerable success. Sunlight is requisite for signalling in this way, the sunbeams being caught upon a mirror and reflected in the direction of the station to whom you desire to signal. If heliostats, properly fixed, are employed, there is no difficulty whatever about this mode of signalling, for the sender has only to work the mirror backwards and forwards, and the receiver to count the flashes of light that come towards him. There is nothing new in this mode of signalling; in fact, savage tribes in North America still practise this means of communicating with one another at a distance. But this is the first instance in modern armies of its use. Some years ago the plan was proposed to our War Office over here, but as the sun is a *sine qua non* to its proper working, it is only in tropical climes that the full benefit can be derived. It is said that the ray of light might be made visible fifty or sixty miles away, the beam shooting so high into the heavens; and, moreover, only those placed at the right angles can see and read the signals. In the Khyber, signals are made right up the Pass to Jellalabad, wherever electric communication does not exist; and according to the testimony of Mr.

Archibald Forbes, the energetic special correspondent of the *Daily News*, the heliostats are worked daily. It might seem at first sight difficult to understand how legible signals are capable of transmission in the form of light flashes, but what is known as the Morse code offers a very easy solution. The dot and dash of the electric code, or short and long signal, furnish in combination any letter of the alphabet, and whether you employ flags or shutters, sunlight or a lantern, the transmission of short and long signals is equally feasible; and with these two signals, telegraphers can understand one another. A little while ago, when the United States forces captured a tribe of Indians, they found upon the chief a hand mirror which had been employed for the purpose of transmitting light signals to a distance. In this case the code must be very crude, and, moreover, the signalling of a rather vague character, for unless the mirror is properly swung in relation to the sun and to the angle of reflection—as upon a heliostat, for instance—one can never be sure of transmitting the signals to the proper quarter. As to the intensity of sun-signals, a very good criterion is afforded at sundown, when the beams strike against the windows of a house or other reflecting surface. The light is so intense that the panes of glass look like burning points, and it is impossible to realise sometimes that it is not a fire one is looking at.

The Photographers' Benevolent Association and its Supporters.—The Photographers' Benevolent Association does not get on as it should. There are plenty of applications for relief, it seems, but not many supporters. At any rate, the members should be counted by hundreds by this time, for it is very certain that there is, unfortunately, very good reason for the existence of the Association. In the early days of its existence, help was given to all alike, whether members or non-members, so long as the Committee were assured the case was a deserving one; but now the Association is in working order, it is only fair, of course, that assistance should be reserved to members alone. The working expenses of the Association, small as they are, are just now out of proportion to its funds, for the simple reason that the cost of carrying on a society must always reach a certain amount, whether it be well or ill supported. The Committee at the present moment, with Mr. W. S. Bird as its chairman, is soundly constituted, and the Association, having now been some years in existence, may be credited with having done its work honestly and well. That there is a reason for its existence is proved by the numerous calls made upon its slender resources, and as the terms of subscription are within the compass of even the most modest income, there is no valid reason why it should not be more energetically supported. If such were the case, we feel sure that well-to-do amateurs and others would not be backward in giving donations and subscriptions, and otherwise aiding a deserving association. But one can hardly expect friends and well-wishers to send their guineas unless they see that the affair has the earnest assistance of working photographers and their assistants, for whose benefit the Association exists; and, so far, photographers' assistants have done little to help themselves.

ON SILVER BROMIDE EMULSION IN GELATINE.

BY CAPTAIN ABNEY, R.E., F.R.S.*

DURING the past few weeks I have had occasion to experiment with gelatine emulsion, and I think that perhaps part of my work may be of immediate interest to the Society. I have, therefore, to state one or two facts connected with the preparation of the emulsion itself, and of the plates. Allow me to say that I do not stand here to advocate any particular plates as known in commerce. My own ideas on the subject are that, *if possible*, every photographer, though perhaps not every photographer, should prepare his own plates, for when using plates prepared by an unknown formula, he often becomes merely a

* Read before the Photographic Society of Great Britain.

mechanical aid to the manufacturer for exposing the plates and turning out negatives, I will not say pictures. It will be seen that I have referred to photographers and photographers as two distinct orders of workers, and perhaps I ought to give my definition of the terms. By a photographer I mean any one who practises photography for what may be termed art or would-be art purposes. By a photographer, I mean any one who adapts photography to science, and uses it as an aid in research. Amongst many of the former, who have not time to prepare their own plates, there are some few who have true artistic instincts, and to them the boon of ready prepared plates to which they are accustomed is great, and they can give their own impress to the pictures they produce, more particularly with plates prepared by the collodion process, where the development can be modified during its progress at the will of the operator. With gelatine plates they have a far greater difficulty to contend with; the negative must, to a very large extent, be at the mercy of the fluid used as a developing agent, and their whole art has to be concentrated in choosing a good point of view, and in watching for an "effect" when exposing. In some directions for development, we are told to immerse the plate in the developer for so many seconds, when, if the exposure has been rightly timed, the negative will be perfectly developed. It is true that for over-exposed and under-exposed pictures we may have supplementary directions given, but the control exercised by the operator over the image is, to my mind, less than in collodion plates, where you can bring up certain portions of a picture according to your liking. For certain applications, where a purely mechanical picture is required, and where, with the same light and the same exposure, an identically similar negative can always be produced, the gelatine plates are most useful, and it is in this aspect that I give them my heartiest support.

Now to come to the preparation of the emulsion. I find that a greater facility in obtaining density is secured by emulsifying rather more silver bromide in a given quantity of gelatine than is usually recommended. The formula I have employed is as follows:—Gelatine (Nelson's photographic) forty grains. Water sufficient to cover it in a beaker.

The swelled gelatine is drained, and sixty grains of potassium bromide are added to it dissolved in one ounce of water, together with ten grains of potassium nitrate. This is gently heated till the gelatine dissolves, when eighty grains of silver nitrate dissolved in one ounce of water are added in the usual manner. The emulsion may now be kept warm up to 90°—according to Mr. Bennett's plan for any time that may seem best. It may then be filtered, and when cooled to about 80° it is ready for coating a plate. This is done in the usual manner, and the plate is laid upon a levelled shelf to set well. It may then be placed in a dish of water for a few minutes, to get rid of the excess of soluble salts, and then in a second dish for a few minutes more. It is next immersed in a bath of methylated spirits free from resinous matter, and allowed to soak for half-an-hour, after which it is set up to dry in a cupboard. After half-an-hour's draining it may be placed in a hot air oven, and in a quarter of an hour or so it will be ready for use. I prefer, however, to let the plates dry spontaneously, as the gelatine is less liable to frill. By adopting this plan I have been able to make an emulsion at 11 o'clock, and to expose plates prepared with it by 2 o'clock. I believe that this method of preparation is about the most rapid that can be adopted, and certainly the plates are very sensitive. It may pertinently be asked if there is any advantage in using an unwashed emulsion. If plates are required in a hurry, there evidently is an advantage, since the time expended in washing the pellicle is thereby gained. Another point, however, is this: if the emulsion be kept in an unwashed state, it does not readily decom-

pose. When potassium bromide and silver nitrate are used, we have potassium nitrate left in the gelatine; as every one is aware, saltpetre preserves organic matter, hence it protects the gelatine in this case. To quote a case: I made some gelatine emulsion in August last, and left it unwashed through an accident, and I am using it now, and find that it is perfectly sweet, and rather better than it would be if freshly prepared. It was left in an open glass jar all these months, and was not dried up in the least, presumably owing to the affinity that this nitrate has for aqueous vapour. The gelatine emulsion may be washed, if thought desirable, and the plates treated with alcohol; and they are not affected, as far as I can judge, by the soaking with the spirit. In hot weather I have had, of course, no experience with this method, but arguing from analogy, it seems that directly a plate is set, and washed in fresh water, if immersed in alcohol, the danger of the gelatine decomposing is very considerably reduced, and we can therefore hope that one source of annoyance in the preparation of such plates may be overcome.

In developing either by the alkaline or ferrous oxalate developer, I always use a small quantity of soluble bromide. It may cause a necessity for a slightly longer exposure, but by its use there is certainly a gain in clearness.

DESCRIPTION OF A CAMERA SPECIALLY ADAPTED FOR THE PORTRAITURE OF CHILDREN AND ANIMALS.

BY JOHN HARMER.*

Those photographers who are well acquainted with the troubles which arise in photographing children and animals will agree with me that almost the chief and most trying one springs from the necessity of having to verify repeatedly the position and focus of the sitter's image upon the focussing screen before an opportunity for exposing is obtained. It often occurs that when all is ready for the exposure—a dog, perhaps, being the sitter—that the animal fancies he would like to take a little exercise, and starts away for that purpose; then, before he is again persuaded to make himself comfortable, the shutter of the dark slide must be closed, then drawn out of position, and the focussing screen passed into its place. After another arranging and focussing, the slide is again pushed forward and its shutter opened, the operations taking sufficient time for the dog to have a recurrence of his fancy, and make off once more.

Attempts to save the waste of labour, time, and, in many cases, temper, have been made in one or two ways, one of which—perhaps the best known—is to have a small finder of the same focus as the lens in use affixed to the top of the camera, and projecting its image upon a small piece of ground glass. This plan, however, is not of much practical value; the small lens does not cover its plate as the lens proper does; it has also another point of view, a matter of considerable importance in some cases.

The plan which I have embodied in the camera upon the table this evening will allow the dark slide to be put into its place, and its shutter drawn previous to commencing the operations of posing and focussing, there being no necessity to cover up the sensitive plate till these operations have been satisfactorily completed, and its proper exposure given. Besides this advantage, there is that of the point of view being the same; therefore the projection of the image for focussing on the ground glass in one part of the camera, and that which is projected on the sensitive plate, are identical in all respects, the image being directed from one to the other by a simple turn of a handle.

These conveniences are obtained by adding to the ordinary repeating camera a kind of upper story, which is

* Read before the Photographic Society of Great Britain.

partially separated from the lower one by a screen of ground glass; above this is placed a mirror at an angle of 45° or so, to enable the image formed upon the ground glass to be viewed by reflection without having to crane the neck over the camera. This mirror may be placed to face any direction, the aperture in the upper portion of the camera being cut in that side of it which is opposite to the mirror. If the assistance of a magnifier be required, one may be made to slide into this opening, and will, no doubt, be a great convenience, because it can always be retained in its place.

In the camera proper, between the lens and focussing screen, or sensitive plate, is placed a sort of box open at the top, the sides of which, extending from the back towards the lens, slope at an angle of 45° exactly from top to bottom. Upon these sides rest a mirror having suitable fittings to admit of its being moved upwards to the top of the camera, or of being lowered till it rests upon the sloping sides of the box as before mentioned. The lifting action of this must be so arranged that the mirror shall travel a short distance in a straight line before the lower portion sweeps upwards through the angle of 45° , for the space between the back of the camera and lens is so limited that if this be not done the lens will obstruct its motion. Lenses of short focus necessitate very careful adjustment, the mirror having to be of a certain size, and its centre lowered till opposite the axis of the lens, there is nothing to spare.

When the mirror is in its first position—viz., resting on the sloping sides of the box—it stops back all light from the sensitive plate, and reflects it instead at a right angle upon the ground glass above, forming the partition between the upper and lower portions of the camera. When raised, it shuts closely over the ground glass, and allows the light to pass onwards to the prepared plate. To ensure the sharp image on the ground glass being equally sharp on the plate, the distance intervening between the lens and the plate must be exactly equal to the sum total of that from lens to mirror, and from that again to the upper ground glass. Both of these mirrors must reflect from their surfaces, or the sharpness of their reflected images will be somewhat destroyed by the confusion arising from the surface reflections, as is the case when ordinary plate glass silvered on the back is made use of. In some cases it would be more convenient to have the lower mirror placed vertically, its movement being horizontal; the image would then be diverted to a ground glass on the side of the camera, and would not need a mirror to view it. The difficulty of so fitting one would be a little greater; there also would be almost a necessity to work with that side towards the opaque one of the studio.

In the original plan of my instrument, it was my intention to place a small bellows, or india-rubber ball, to be squeezed by a lever acted upon by that which lowers the mirror just as the sensitive plate was entirely screened, then one motion of the handle would serve to lower the mirror and uncover the lens by forcing air into the pneumatic shutter; but through not purchasing this latter accessory till the construction of the instrument was too far advanced for alteration, I found that adequate space had not been provided for to secure a sufficient amount of air pressure for the purpose.

With respect to the fitting up of cameras with the above additions, it appears to me that most rigid repeating cameras at present in use might be readily altered to answer the purpose. Such, as well as all new ones, would be practically of the old form by simply raising the mirror, each one being provided with a focussing screen in the dark slide frame.

The one I have here is perhaps too elaborate for use in the studio, but having been my own mechanic (and an amateur only), except in constructing a portion of the brasswork, you will understand it has been a pet, and will perhaps excuse any errors or defects of fitting that a more

skilled artisan would have avoided. Many points I should be able to improve upon in the construction of another; this, of course, being the first, can only be considered an experimental one. The mirrors in it are of ordinary silvered plate glass; these I have been obliged to make use of for the evening through having been disappointed in not receiving the others in time; they quite serve, however, to illustrate the principle I have adopted.

DUPLEX DROP SHUTTER.

BY W. BEDFORD.*

So many ingenious plans have been devised for giving rapid exposures that I feel that some apology is needed for bringing before you this evening a contrivance of my own, which, however, if not superior in principle to any hitherto introduced, has the merit of simplicity, and I think it will also be found to do its work efficiently.

BACK VIEW.

A A, B B. Two similar metal discs pivoted at C. D. Ring adapter fitted to mount of lens. E. Centre of lens. F. Weight attached by silk cord to each disc. G. Trigger with cord attached, fitting into notches II. When the exposure is completed, the stop at I comes in contact with an overhanging hook, near the trigger, which also serves to keep the discs in contact.

It is essentially constructed of two heart-shaped metal plates revolving on one axis, which is attached to the lower part of the mount of the lens. These two plates, when released by the trigger, have a reciprocal motion imparted to them by means of the weight which hangs suspended from the upper part of each. The apertures in each plate are thus simultaneously brought in front of the lens, and the exposure rapidly effected. You will observe that the exposure commences and terminates at the lower side of the centre of the lens, so that the foreground will get slightly more light than the upper portion of the picture, an advantage which will be readily appreciated by most photographers. It will be seen that the exposure may be easily accelerated by the addition of extra weights. I have not yet had an opportunity of testing its rapidity, but I purpose doing so by photographing a pendulum of suitable length oscillating within a given arc. It will then be only necessary to read off from the resulting negative the number of degrees traversed by the pendulum during the exposure, to arrive, by a simple calculation, at its duration. If any member present can propose any more trustworthy test, I shall be glad to have the advantage of his suggestion.

ON ALBUMENISING PLATES.

BY E. WORMALD.†

An old author says—“When all is summed up, a man never speaks of himself without loss; his accusations of himself are always believed, his praises never.” Though the means used by all of us are for one end—good pictures—we may

* Read before the Photographic Society of Great Britain.

† Read before the West Riding of Yorkshire Photographic Society.

still differ greatly in the modes used to obtain them, and I am egotistical enough to prefer my own.

To begin with the foundation of all our work—glass: any sort will do if only flat and clean. I have taken pictures 12 by 10 on common window glass, when no other has been obtainable, which have been enlarged to 26 by 21, specimens of which I now show you. I am now using plates which have had pictures on their surfaces for twenty years, and the few scratches which may be on them are not to be seen in the finished negative. I steep all my glass, new or old, in sulphuric acid and water tolerably strong. I think it leaves the surface of the glass brighter than any other acid. I place them in a flat dish, remaining there till I want to albumenise them. Various mediums have been suggested as a substratum, but above all is albumen. There is nothing like it for the tenacity with which it holds the collodion film on the plate. I have washed my plates, 12 by 10 to 26 by 21, after development, in all sorts of water—stagnant bog water, that from dirty rivers, becks, yellow ponds, even water from coalpits and clayey tunnels, and which has been poured on at varying degrees of pressure, over rocks, mill weirs, from buckets, and even under the water from a hose pipe; in fact, I have washed them in every sort of place where water could be plentifully obtained, and never once have had a blistered film, or a film washed off, for the past sixteen years that I have used this substratum on the plates.

To prepare it: put the albumen of one egg into a twenty or thirty ounce bottle and add to it half an ounce of pure ammonia, .880. Shake it up gently every hour or so, and let it stand over night; in the morning add one pint of water, and shake up gently to make as little froth as possible, when you will find the albumen thoroughly combined with the water. If you allow the albumen and ammonia to remain together for a day or two before adding the water, it will be all the better. This pint of solution will coat one hundred and fifty new 12 by 10 plates. If the plates are old ones, add only ten ounces of water; the albumen being thicker, seems to fill up the scratches.

The water for washing the plates must be perfectly clean. If it flow from a tank it will probably produce gritty spots, as the continual flow of water seems to disturb the sediment at the bottom of the tank, in which case (as has been suggested by some one else) a good plan is to flow a little distilled or filtered water over the plate before pouring on the albumen, which must be applied so as to make the water flow before it and drive off all bubbles.

I once read the remark that the albumenising of plates was a mere plea for laziness. This I deny emphatically, as no amount of cleaning with cloths or leather, spirits of wine, rouge, French chalk, glycerine, oil, or (as has been suggested) even a tallow candle, will produce a plate that will stand the usage some of my plates have to undergo; and I simply use "elbow grease" and patience in rubbing the plates with a clean cotton rag and acid, wash, and albumenize.

You must pardon my being so prosaic about this matter of substratum, which has been so much chased "up hill and down dale." In the face of the new quick dry processes I feel as if I had just come "in at the death;" but it is to me a matter of vital importance in connection with large plates, long exposures, and hot weather.

What bad effect it may have on the nitrate bath I know not; but if you set the little ammonia that may possibly get into it against the many other things added to the bath—nitric acid, hydrochloric acid, cyanide, permanganate of carbonate of potash, soda, nitrate of barytes, and now nitrate of lead—I think it can do very little harm. Practically I find none.

Speaking of the bath: I may say that, for outdoor work, I prefer a large-sized, middle-aged bath, which you can rely upon (I care nothing for your new skittish bath whose action is so uncertain), a chestnut-coloured collodion, with a brown developer gentle and slow in its action; then, with a plate well and carefully albumenized, you may be certain of securing a really good negative, which you may wash and fix out of doors and treat in almost any way you like.

NEW AUTOMATIC SYPHON.

BY DR. WILLIAM TAYLOR.*

This is an apparatus designed to serve as an overflow pipe to tanks or other vessels not already fitted with means to that end, and without in any way altering these vessels. It is specially applicable to tanks with a fluctuating supply of water, but in which the water must be maintained at a constant level. As its name implies, it is self-acting, and while at once carrying off any sudden influx of water, it will not bring the level below a certain fixed line. The excess of water is carried from the bottom of the tank. Into the tank, T, is passed the waste-pipe, A B, of a diameter greater than the feed to the tank. This waste-pipe is bent into the

form shown, with the shoulder, S, about half an inch lower than the level of water required in the tank. In the upper surface of this shoulder, at S, a small hole is made, over which a small tube is fixed. This small tube, S L, is then led over the side of the tank to the constant level, L, required.

When this waste-pipe is put into action as a syphon, it rapidly carries off the water to the level, L. When it reaches this, air is admitted by the small pipe through the orifice at L, and the waste-pipe ceases to be a perfect syphon. If, now, a small stream of water flows into the tank, the same quantity passes through the partial syphon, A B; but should a rush of water into the tank take place, bringing the water above the level, L, the waste-pipe is at once converted into a true syphon, and rapidly brings the level back again.

In the sketch, the pipes have been drawn projecting from the sides of the tank, but of course, in practice, these pipes are laid close to the side of the tank.

LIGHT, AND ITS WORK IN ABSORPTION.

BY CAPT. W. DE W. ABNEY, R.E., F.R.S.†

We can now talk of radiation as light, if we make the proper reservation, and as such I shall henceforth designate it, as it will be more popularly understood.

I have already asked you to imagine that the vibration of a particle (and when I say a particle, I might have said any number of particles) in a star or in the sun can set this medium in motion; but in any hot body, whether distant or near, the same occurs. Thus the particles in these gas flames are causing undulations which reach the eye when it is directed towards them. Let me broadly state that when I talk of particles, I mean very small—almost infinitesimally small—component parts of a body, and it is these particles which are surrounded by the ethereal medium to which they communicate their vibrations. Now, the natural questions to ask are, Are all bodies hot? What are hot bodies? And, Whence do they derive their heat? I may answer the first question by saying that everything terrestrial, at all events, is a hot body; and the second by saying that as long as there are internal vibrations in the body, so long is the body hot when measured by scientific measure. There is a theoretical zero of heat at which all bodies would cease to have any internal movement of their particles, and then it would be

* Exhibited before the Edinburgh Photographic Society.
† Continued from p. 79.

that we could say we had a body perfectly devoid of heat. The late frost has, perhaps, called to mind that we have been suffering from what we call cold, and at first sight it may seem wrong to say that ice is a hot body. What gives us the sensation of cold? If we place one hand near a piece of ice, we feel that cold, as it is called, is given off. It is simply that we are hotter than the ice, and the vibrating particles of our body set in motion the ether. These vibrations are stopt by the ice, and the energy carried by them is expended in warming it. The atoms of ice are likewise vibrating, but less vigorously than our bodies, consequently we expend more work in warming the ice than the ice does in warming us. If we did not keep up a store of energy in ourselves by eating food, which in its turn causes a renewal of the work expended on the ice, we should gradually become of the same temperature as the ice.

But both the ice and our bodies are warm compared with the absolute zero of temperature, which is some 270° below the freezing point of water; and it is only at that temperature when a body can be said to be without heat—that is, to have no internal motion to communicate to the other. Perhaps this low temperature may exist in space, but we have never felt it, and if it could be brought down to this earth, the aspect of nature would be changed.

The last question, From whence do bodies derive their heat? has yet to be answered. Primarily from the sun, and then from one another. The sun shines, and falls on bodies which may be opaque, such as the earth; or only partially such as the air. The waves of ether are stopped by them, and the result is that their particles are put in motion, or, in other words, they become heated, and they are capable of giving out radiation in precisely the same way as is the sun. The sun, the gas, the table, myself, are all sources of radiation, but, as is self-evident, all are not sources of those peculiar kinds of radiation which cause the sensation of light.

The fact that we can see objects depends upon one of two things: either they must emit radiations which give us the sensation of light, or they must reflect light from some source which emits the same class of radiations. We shall see later how it is that bodies appear coloured when illuminated by white light, that is, when they reflect certain radiations contained in that light.

Recollect, then, that any body whatsoever is in a state of internal commotion of so minute a character that it cannot be perceived by our coarse senses, though its effects are manifest to us. Nothing is at rest on this earth; the whole of the matter of which it is composed is in motion; nature is in a state of unrest.

Then you see that the hotter a body is the more restless it is, and when it becomes very hot, the waves are generated by its particles of such a strength and character that some of them are able to do work, as I have already said, in our eyes, and give us the sensation of vision and colour. Thus in a gas flame we have the particles in a state of active vibration, and in the electric light we have them more active still.

It is with this last source of light that we have to do. On the screen you now see two glowing points. These are, in reality, the images of the ends of two graphite or carbon rods, which have been put in a state of intense molecular vibration by the work executed in them by means of electricity (we shall see further on that this same energy is capable of doing different work), and that they radiate waves in the ether of almost every possible length.

Now, I am not going to enter at all into optics. I must ask those who do not know their principles to take their theory as being capable of rigid proof, whilst the demonstration of their properties will aid them in their belief. In front of this light, which is enclosed in a lantern, I place a lens, and in front of the lens is a slit through which the light collected by the lens passes, and in front of this another lens to collect the rays and focus them on the screen. If I send such a slice of light through a prism, it becomes bent, but bent in a peculiar manner. The whiteness dis-

appears, and we have a band of gorgeous colours appearing on the screen.

Here we have it [spectrum shown], and now I will at once state that the lengths of the energy-carrying waves vary at every minute part of the width of that gorgeous band. When I say length of the wave, I mean the distance between the crest of one wave and that of the next. The waves travel over the same space, however, in a given time, and as the red light has the longest wave length, and the violet the shortest, we come to the conclusion that many more waves of the latter than of the former must strike the eye in a second. But on this I do not wish to linger. I only want you to remember that each part of this lovely variegated band is formed by energy carrying waves of every shade of length varying between 1-40,000th of an inch and about 1-60,000th of an inch, and that these lengths alone cause vision.

It is to radiations within these limits that I wish to confine your attention to-night, though there are radiations which the prism has separated out, which are not visible to us, which lie above the violet, the wave lengths of which may be as short as 1-180,000th of an inch, whilst below the red there are other radiations which certainly have wave lengths as long as 1-20,000th of an inch. I may remark that the radiations from the bodies at ordinary temperatures have these long wave lengths. I will show you that these colours, where mixed, give us the sensation of white light. In this wheel we have seven of the colours into which white light may be roughly divided. On the screen they show in their true brilliancy. I rotate the wheel, and we have a nearly white patch.

(To be continued.)

COPYRIGHT IN PHOTOGRAPHS AND DESIGNS: IN CHANCERY the following case was heard:—

Adams v. Clementson.—The plaintiff in this case was William Adams, of Tunstall, in Staffordshire, a manufacturer of earthenware, and the defendants were Messrs. Clementson Brothers, also manufacturers of earthenware. The action was brought by the plaintiff to restrain the defendants from manufacturing or selling any articles of earthenware having applied thereon the design of the plaintiff, registered on the 17th July, 1878, consisting of the portrait of General Martinez de Campos, Captain-General of Cuba, surrounded by a wreath. It appeared that orders had been received by both the plaintiff and the defendants to supply earthenware plates and other articles for the Cuba market, and they had both been supplied with photographs of General Martinez de Campos, to be copied and used as designs upon the various articles. The plaintiff registered his design as a new and original design under the Copyright in Designs Acts, 5 and 6 Vic., cap. 100, sec. 4, and 13 and 14 Vic., cap. 104, sec. 8, and now claimed that the defendants were not justified in infringing his design.

Mr. Higgins, Q.C., and Mr. Herbert Smith, appeared for the plaintiff, and moved for an injunction.

Mr. Glasse, Q.C., Mr. Ashton, Q.C., and Mr. Ingle Joyce, were for the defendants.

The Vice-Chancellor said the question was whether the design of the plaintiff came under the definition of a new and original design within the meaning of the Copyright in Designs Act. His Lordship had no doubt that the defendants only intended to do what they were justified by law in doing. It appeared that the plaintiff had received an order for the supply of a considerable quantity of earthenware, to be sent out to the Cuba market, and he was requested to have the portrait of General Martinez de Campos designed upon the plates and other articles to be manufactured, and for this purpose he was supplied with a photograph of the General. A copy of that photograph was consequently designed and placed upon these articles, and he now asked that the defendants might be restrained from adopting the same design. The defendants, it appeared, had also received an order for earthenware, and had been supplied with another photograph of General Martinez de Campos, which was to be designed upon the articles manufactured. The plaintiff claimed this portrait as a new and original design. It was, no doubt, very important that trade should not be embarrassed by unnecessary restrictions, and if every man who merely copied a well-known portrait and placed that upon the articles he sold, could be restrained by this Court, it would have the effect of paralyzing trade. The plaintiff had taken the photograph and copied it, and so also had the defendants. There was nothing new or original in either design. It was an abuse of the terms of the Act to call this a new and original design, and he should refuse the injunction, with costs.

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

THE average number of hours a day in which good daylight prevails in this country is considerably smaller than even the most rabid stickler for short time in days-works would think of demanding. It is certainly much smaller than meets the convenience of the working photographer or professional portraitist, and there are few, we apprehend, who, when an important customer entered the studio during the declining hours of an autumnal or winter's day, have not earnestly wished that they could turn on some available succedaneum for daylight. The existence of artificial lights of considerable actinic power has been well known; but hitherto the difficulty of securing with such lights the same conditions of equal illumination which characterise daylight have been found insuperable. It is tolerably clear that to secure a satisfactorily pictorial result, and a familiar and effective likeness, the conditions of light and shade must be as nearly accordant as possible with those commonly prevailing, and under which people usually see their friends. Hence illumination proceeding from one intense centre produces shadows unfamiliar in form, and unpleasing and unnatural in blackness. Attempts have been made with magnesium, with electricity, and with pyrotechnic compounds to produce light for portraiture, and to govern or modify them by means of reflectors. But the methods have been troublesome, and the results unsatisfactory; none of these have, therefore, come into practical use.

The first apparently satisfactory method which was brought to a practical issue was Vanderweyde's mode of using the electric light, in which the rays spreading from a point were gathered by means of a huge dioptric lens into a large cylinder of light, giving practically the effect of parallel rays. The machinery was, however, too costly to present any likelihood of coming into general use, and something therefore still remained to be done. The next candidate for the approval of photographers was the method adopted by Messrs. Alder and Clarke, their apparatus being patented under the name of the *Luxograph*. We do not in any degree intend to depreciate the contrivance when we say it appears to be an ingenious combination of previously existing ideas. Thus the light is derived from the burning of a pyrotechnic compound resembling that used twenty years ago by Mr. Moule, and the means of reflecting and diffusing the light produces an effect not unlike that secured in Vanderweyde's mode of using the electric light. A measured quantity of the compound is placed in a burner, which is provided with a flue to carry off the products of combustion. A huge concave reflector throws the light on to the sitter, and its intensity is tempered by passing through a diaphanous screen placed in front, the light being between the reflector and the screen.

The working of the arrangement, so far as we can judge, is very satisfactory. The lighting on the sitter, when we inspected the working, was excellent, giving fine modelling, and entire absence of the hard, abrupt black shadows commonly associated with artificial lighting. The exposure will vary, of course, with the nature of the lighting material employed. Messrs. Alder and Clarke use something in the nature, we believe, of what is known as the Bengal light, used for signal fire, and, if we remember rightly, the exposure was about twenty seconds. Some portraits before us are not inferior to daylight pictures; one of Mr. Glaisher, the President of the Photographic Society, now before us, is an admirable portrait and an excellent photograph.

The subject of Messrs. Alder and Clarke's patent has no relation to the light employed, but to the mode of controlling it; the combination, in fact, of reflectors and screens constitute the *Luxograph*. There remains, therefore, a wide field for investigations and experiments to determine the most efficient and available light, and something may yet be done in trying modes of applying artificial light. Hitherto the artificial light has always been introduced into the studio, or into the apartment where the sitter was placed, and the fumes emitted by many of the burning materials employed have been a source of constant trouble. Burning magnesium, for instance, emits an exceedingly actinic light, and, directed and controlled by an arrangement like the *Luxograph*, would probably be found very efficient; but the dense fumes produced by its combustion have been sufficiently troublesome to be almost prohibitive as to its use. The fumes ensuing from many of the pyrotechnic compounds, some of which contain arsenic, are more offensive and dangerous still. The question very naturally arises, then, as to whether the introduction of the burning materials into the studio is necessary. The photographer's studio is generally built so that the light falling through a given space of the window shall duly illumine the sitter. Is it necessary to give up this facility in using artificial light? If the light—say a pyrotechnic compound—be fired outside the studio, opposite the window, duly arranged to light the sitter, an effect of lighting closely resembling daylight illumination might be obtained, whilst all noxious fumes might be confined to the open air, whence they would be quickly dissipated. A due arrangement of reflectors behind the light, and of diaphanous screens in front, might be used, or the window of the studio might be covered with thin semi-transparent blinds to soften the intensity of the light. It would be well, in making experiments of the kind, to select a private neighbourhood, or an alarm of fire might easily put an abrupt termination to experiments.

The selection of the most convenient, efficient, and safe means of securing an actinic artificial light is a matter of considerable importance which has not hitherto received much systematic attention and investigation. New lights have been announced from time to time, and some investigations have been made, but the absence of efficient means of applying such lights to portraiture has prevented general and systematic research. The chief sources of artificial light are found in the combustion of certain metals and metallic salts. It has been alleged, indeed, that the source of solar light is due to the intense combustion of certain metals, such as chromium, magnesium, and titanium, at the sun's surface. The Bengal light is obtained, for instance, by igniting sulphide of arsenic and antimony, or nitre. A very intense and actinic light is obtained by the spontaneous combustion of phosphorus in oxygen. A very actinic light is obtained by the combustion of sulphur in saltpetre heated until it melts. The usual method of obtaining this light, by first melting nitrate of potash in a crucible or mortar, and then throwing in pieces of sulphur, is not unattended by danger in inexperienced hands. But if the powdered nitre, quite dry, be placed in a suitable vessel, and then press into the

surface of the powdered salt a piece of phosphorus, and ignite it, the heat will melt the nitre, which will evolve oxygen sufficient to combine with the phosphorus, and produce a very intense white light. This is, practically, a combination of the phosphorus in oxygen method with the sulphur in nitre process, as efficient as either, and more simple. It is not improbable that the oxy-hydrogen light with an arrangement for connecting the diverging rays into parallel rays might be found to answer. To give the oxy-hydrogen light a bluer and more actinic quality, M. Carey Lea has recommended soaking the lime cylinders in a saturated solution of sulphate of copper.

We may conclude by restating the comparative actinic values of some artificial lights as estimated by Messrs. Riche and Bardy, who some time ago undertook an investigation. In these experiments, the oxy-hydrogen light stood lowest, and is numbered as 1. Thus—

Oxy-hydrogen light	1
Drummond light	3
Zinc burnt in oxygen	3
Magnesium	5
Current of binoxide of nitrogen in a flask containing bisulphide of carbon	6
Jet of binoxide of nitrogen upon a vessel containing bisulphide of carbon	6
Jet of oxygen upon a vessel containing bisulphide of carbon	7
Jet of oxygen upon a vessel containing sulphur	8

THE "MONITEUR DE LA PHOTOGRAPHIE" AND ERNEST LACAN.

THE last number of our contemporary, the *Moniteur de la Photographie*, contains a notice that, pending arrangements which await completion, M. Leon Vidal will superintend the editing of its columns. The new number opens with an eulogy by M. Vidal on the late proprietor and editor of that journal, M. Ernest Lacan, our own valued and lamented contributor, which we translate for the benefit of our English-speaking readers.

"With the profoundest grief and feeling of sorrow, we announce to our subscribers and readers the death of the eminent founder of this journal, which he conducted with so much perseverance and acknowledged talent. Ernest Lacan is no more. He succumbed suddenly and unexpectedly to a second attack of the same complaint that during the course of last summer already placed his life in danger. On that occasion, thanks to skilful advice and to tender and unwearied care, he was able to resume almost unchanged his ordinary course of life—a life devoted to his relations, his numerous friends, and to the science that he loved so well.

"It seemed as if he would still be able to do much for that science, and rejoiced at the ever growing success of his work, to which he had given eighteen years of his life. He expressed in this journal, only a few weeks ago, his pleasure at having been able, thanks to the numerous visitors to the International Exhibition, to reorganize the strength of the bonds that the *Moniteur de la Photographie* had created between his friendly readers and himself. And then he went on, as if oppressed with a presentiment of the fate that has snatched him from us: 'We have always been of opinion that the aim of the editor of a journal like this is to instruct its readers, to give them information on every point which bears on the practice of their art, and to collect with care and diligence, but without partiality, all the facts which can possibly be of interest for the same purpose. The success that we have attained is a proof of the correctness of our judgment in adopting and faithfully adhering to this programme, and we shall be careful not to make any change in it.'

"It remains only now for us, his devoted fellow-workers,

to pursue the line of conduct which this best of friends had traced for himself. We must all endeavour to remember the gratitude that we owe to one who was always eager to sustain and encourage our faltering steps in the path of discovery and invention; and this gratitude must not be limited to regrets, however sincere they may be. We have before us the task of watching over his labours, and of preventing them from being forgotten. It must be our part to take care that his name should receive the tribute of remembrance and praise of which it is so worthy; to see that it be inscribed in the historical roll of scientific progress with which it has been associated for more than five and twenty years.

"Such is the duty of us who are left to mourn his loss. Let us fulfil it with the same ardent faith in the brilliant future of the photographic art that he always professed; let us continue to record here, and even to exalt, every success of his beloved science, and we shall thus not only be faithful to his revered memory, but shall also, if such be possible, help to assuage the grief and wipe away the tears of the loving and brave companion of his life—of one who, not content with surrounding him with with every care and affection, made herself his assiduous fellow-labourer in his scientific work."

FRENCH CORRESPONDENCE.

DEATH OF M. ERNEST LACAN—PHOTOGRAPHIC UNION OF FRANCE—PHOTOGRAPHY BY THE ELECTRIC LIGHT ON THE SYSTEM OF VANDERWEYDE—PROCESS OF PHOTOGRAPHING IN COLOURS—PHOTOGRAPHIC LITERATURE.

Death of M. Ernest Lacan.—During the last month the photographic world has been at the same time startled and pained by the news of what may be called the sudden death of M. Ernest Lacan, caused by a second attack of an illness of which he appeared to be cured. The life of our lamented colleague was devoted to the promotion of several branches of applied science, and photography more especially occupied a large and prominent place in the catalogue of his researches. Eighteen years ago (in 1861) M. Lacan started his own paper, the *Moniteur de la Photographie*, and although he worked assiduously on the staff of several other journals published by the *Societe des Publications Periodiques*, it was to the first named that he directed all his care and enterprise. During this period he was thus completely associated with the progress of photography—that inexhaustible science which produces every day a fresh surprise in the way of novel discovery or further application. In his capacity of correspondent of the PHOTOGRAPHIC NEWS he had for a long time given most commendable proofs of his acquirements; in the place which he occupied up to a few days ago, I venture, with feelings of profound grief for his loss, to offer a humble testimony of respect and esteem to his memory. Ernest Lacan was not merely an enlightened and indefatigable worker, whose death has left a void difficult to fill; he was also in private life an amiable and kind-hearted man, who was always ready to render a service, and had the faculty of attaching to himself a number of sincere and sympathizing friends. In its last number the *Univers Illustré* publishes a portrait of our late respected friend, whose place I have taken as Correspondent of the PHOTOGRAPHIC NEWS, but with the well-grounded fear that I shall never be able to replace him.

Photographic Union of France.—Nothing is in closer relation with death than life; and there is in effect a new life stirring latterly in the photographic world here. In the PHOTOGRAPHIC NEWS of the 27th of December last, the proposed formation of a new association was mentioned, and this association has now been definitely established under the name of the *Union Photographique de France*. The statutes of the Association have been drawn up and circulated among all the professional and amateur photographers, with an earnest appeal to them not only themselves to become members of the Union, but also to

induce their friends to co-operate efficiently, cordially, and loyally in promoting the numerous and important interests of the photographic art in France. These are the actual words of the circular issued by the directors of the Association, and they add that in drawing up the statutes they have been at great pains to work according to the principles of good fellowship, in order to avoid all spirit of cliquism, and to satisfy the real wants of the profession. The executive council of the Photographic Union consists of the following members:—M. H. Collard, president; M. Baccard, jun., vice-president; M. Liebert, treasurer; M. K. Versnaeyen, secretary; together with M.M. E. Carjat, Delie, and Gougenheim. In the new society elementary courses of instruction in chemistry and technical drawing will be organised; it is also proposed to start a special journal, but until that proposition is carried into effect, the *Revue Photographique* will provisionally be looked upon as the official organ of the Association.

The Electric Light in Photography.—Many photographers are at present losing their heads over the use of the electric light in their art; every one, more or less, is either employing it or studying it. M. Liebert has acquired in France and Belgium the sole patent rights of the system of Vander Weyde, of London, and, with the practical sagacity of a thorough man of business, he has advertised his new arrangements with much liberality and skill. First he invited all the correspondents of the press to witness his introductory experiments, and then he secured the attendance of a group of visitors of distinction; among others, portraits taken by night of H.M. the ex-Queen of Spain; of General Grant, the late President of the United States; of General Noyes, the American Ambassador in Paris, are exhibited by the side of those of a number of Parisian celebrities in many a grand show-case along the boulevards and the principal streets. In addition to his, last Tuesday M. Liebert gave a large soirée to which more than 800 persons—all of the upper tier—were invited. To dazzle all these people, portraits were actually taken by the electric light; and, in the midst of music and dancing, the general topic of conversation was this new process, which the youngest child of M. Liebert—a boy of three years old—calls “le soleil de papa.” In addition a *Ronde diabolique* was sung with chorus and orchestral accompaniments entitled “Photography and Electricity.” All this is the amusing side of the question; but if it be true that the sun has found a powerful rival in the electric light, and that the latter only wants to be thoroughly worked out, it is not less true that photographs cannot always be taken at the height of a popular fête. It is not, therefore, surprising that M. Liebert prefers to work in the calm of his own studio. We have seen him operating under these conditions, and can testify that the results he obtains are excellent. The light is transmitted from the electrical apparatus by double reflection by means of a disc which projects it on a large elliptical reflector, where the rays are concentrated, and thence diffused into space. It is this arrangement which gives the light the same quality as that of daylight, inasmuch as it does not illuminate the object directly. There are consequently no hard outlines, no exaggerated shadows, no offensive and false inversions, as in the old system with direct illumination. The light is produced by an electro-dynamic machine of Gramme, with an illuminating power of 500 Carcel gas jets; this is set in motion at the rate of 500 revolutions per minute by a gas engine of four-horse power. The effect produced is very much like that of the light of the sun after traversing a white mist, and this, as is well known, is very actinic. The fuss made about the electric light will be the cause of many disappointments. Already several photographers, both in Paris and the provinces, are rivalling each other in advertising their experiments, only they forget to mention that they work on the old methods. They have, therefore, merely a cart without a horse, and are like the ape in the story who

tried to show some pictures with a magic lantern, but forgot to light the lamp. The electric light alone, no more than the light of the sun, is not sufficient to produce good portraits; it requires, besides, considerable skill and good apparatus. By this I do not mean to say that all electric-light photographers are antagonists to progress, and only work the light by the old methods. On the contrary, M. Lumière (a most appropriate name), of Lyons, has also adopted the Vander Weyde system, and the firm of Ghémar, in Brussels, states its intention of immediately following his example. Courage, photographers! You will soon have no cause to be afraid of bad weather.

Photographing in Colours.—Another triumph for photography is signalised in the invention of M. Germeuil-Bonnaud, of Paris. The English public who read *Truth* are probably not able to understand entirely the meaning of the following paragraph, which appeared in No. 103 of that journal of the 23rd January last:—“I have been shown a very marvellous specimen of a coloured photograph. The inventor is a Freuchman. The photographs are not taken directly in colours, but they are not coloured behind, and when the process is introduced in London, as the photographs are hardly dearer than those now sold, it will, I think, revolutionize photography.” This relates to the invention of M. Germeuil-Bonnaud, the ingenious discoverer to whom we owe so many improvements in the process of photographing on porcelain, and who has now succeeded in obtaining the direct action of photography on different colours. All that he has done is to sensitize the neutral colours, and to render them insoluble. The coloured proof leaves the bath ready to be delivered to the public, and the supplementary operations of mounting and enamelling do not cause the slightest injury. The advantage of the process is manifest: first of all, there is no question of a gelatine film covering a plate of colour, or of some medium, by transparency; the colours and the photograph form one and the same body. As regards cost, the prints in colours are not much dearer than ordinary photographic prints. This is not, it must be confessed, a process for taking the natural colours direct by photography; but, *en attendant* that they can be taken as they appear in the camera, the process of M. Germeuil-Bonnaud is an immense stride in advance for colour photography. There is no need for the hand of a skilful artist to apply these colours—which may be in water-colour or any other medium—on the photographic prints; a child can now lay them on before printing, and it is only necessary to have a good negative to obtain a beautifully coloured picture, whether of a portrait or landscape, an object of art, or any other reproduction. More especially for art objects, the invention of M. Germeuil-Bonnaud will be found to meet a great want.

Photographic Literature.—In the field of photographic bibliography several new publications have been welcomed with eagerness. Among them are the third and enlarged edition of M. Liebert's *Photographie en Amérique*; the excellent YEAR-BOOK of Mr. Wharton Simpson, of London, as useful as it is interesting; and the catalogue of M. J. Audouin, of Paris, which contains not only a price current of every photographic requisite, but also much good advice, and many excellent hints. This catalogue possesses also an interest of its own, inasmuch as it makes known to the public several entirely new processes.

Correspondence.

OXALATES IN PHOTOGRAPHY.

SIR,—I read with pleasure a letter in your last signed “A Looker-on,” who is kind enough to remind me of a letter of mine published in the PHOTOGRAPHIC NEWS, some time ago, after a note by Sir John Herschel in the same

journal. I confess I had entirely forgotten it. Nevertheless, it shall, with your permission, be the opportunity for stating that I have great faith in the future of oxalic acid, or oxalates, as applied to photographic processes; hence I was pleased to see reference made by several of your correspondents lately to my first experiments in this direction. Still this experiment of mine was only a rude attempt to imitate silver prints and to substitute iron for silver. It might, perhaps, be worked out into a thoroughly artistic process; but I rather fancy Mr. Willis has struck upon the right track—as far as delicacy is concerned, more especially—and I should not be surprised to see some modification of his process prove successful in emulsions. Some compound oxalic ethers, either combined or mixed, with certain compounds of iron, might find their way into colloids, &c., more readily than the chloride or bromide of silver mixtures now in use.—I am, yours, &c.,
London, Feb. 14th. T. L. PHIPSON, Ph.D., F.C.S.

PYROTECHNIC COMPOUND.

SIR,—I think the undermentioned will answer all the requirements of an actinic compound as requested by Mr. Faulkner, having used it twenty years ago successfully for map and plan copying. I should say, with a rapid lens and sensitive bath, eight to ten seconds should suffice.

Black sulphide of antimony	...	12 parts
Sulphur	42 "
Nitrate of potash, by weight	112 "

Well dried and pulverised separately, then passed together through a hair sieve.

I shall be happy to give any further information required.
 SCOTIA.

PORTRAITURE BY ARTIFICIAL LIGHT FOR AMATEURS.

DEAR SIR,—May I ask the Rev. H. J. Palmer, through the medium of your columns, to explain more definitely the means whereby he gets rid of the "smoke nuisance" in the lamp he suggests. To me, a professional (and professionals, perhaps, may be allowed to take an interest in these matters equally with amateurs), the method does not appear sufficiently lucid; and possibly I may not be the only one who cannot "see it." The idea seems an ingenious and likely one, and, as a matter of experiment, I should like to carry it out as accurately as possible.

While on this subject of artificial lighting as applied to photographic portraiture, I would remark that I, for one, shall never be in favour of its application for establishing *night business*. I think photographers, as a rule, have enough to do and to contend with in their *daily struggles*, without seeking to shorten their frail lives still further by running after this "ignis fatuus," and finally making it their ideal and their god, which very many would do if once they began the "pursuit" of such "pleasure?" The result of this can be no *real gain* in the long run, as photographers are very like sheep in these matters—if one starts all will doubtless follow, to their bodily if not spiritual ruin. But I trust it may not be so, and that we shall have none of it. Surely photographers, above all others, need an amount of recreation and rest after their peculiarly harassing and fatiguing *daily labours*, without establishing a "night season" to finish them off entirely.

Artificial light for use on dark days, and occasionally at night for anything "special," also for printing, copying, and enlarging during the present *usual hours*, will, without doubt, prove exceedingly useful, and be a great acquisition to the professional photographer; but, on the other hand, if its powers and uses are to be abused after the manner I have set forth, placing us on a level with third-rate shopkeepers and "restaurant" proprietors, I should deeply deplore and strongly denounce its introduction. For my own part I should feel inclined to resign the profession at once, and

start in some other line altogether. As for assistants, I am sure they'd "stride" in a similar direction without stopping to think.—Yours truly,
 VINCENT HATCH.
Huddersfield, February 18th.

A PRELUMINERY NOOTIZ.

MISTER HEDTUR,—Praps you woant mind my interduen myself tu yow wooth a few thouts wot i hev bin a thinkin lately, my pore owl fayther use to sah tu me boi sez he "you mark my wurd thez more munney got by skamin then there iver waz by hud work ain ime blowed if i doant think as how he wornt fur out; ye noo i hev been a watchin things a bit lateley, an i fare tu think i hev larnt how tu du it, anyhow i mene tu hev a slap at it thow i am a gettin as ma sah inter the arternoon. i thout i wud jist rite an tell you about it beez you mite like tu go snax wi me. i spooz you noo wot that mene doant ye, if nut ull jist tell ye, it mene tu shere an shere alike doant ye see, an praps it wud be as well if we had 2 or three more in it as tha sah doon here "the moor the murrier," so if you can spot 2 or three sharp sort o' ehaps jest you horl em in wool ye, or if you think we ortent tu du that till arter we begin bizness du so i arut at orl petickellar, i hev bin a thinkin we shull hev tu hev a rume sum wheres in lunden leastways you wud korl it a norfis i spooz; but i shall get use tu yer lunden ways when i eum up and sune be like a pare o' wellurton botes with plenty o' da an martiu on 'em; ower slister doou here have got a gret bit o' brass nailid on tu his door with his name writ on it, we mite hev oue like that and hev theze ere 3 names on it, Mussers Trapein, Catchem, an Skinem taste-o-money-all-aygents. there now you see my little game doant ye an wot du you think ont? tiz the sound o' the munney wot'll drack artenshun, but this you noo is ony a gieneral sort o' outline and i karnt tell you eny more now becz ime bizzy a makin a new paytent masheen tu put into the bizness so as to make a bigger consarn on it. an that i rekkon wool be the larst bit o' hud wurk i shill hev to du for thatll bring in a fortehin for the lot on us but ull tell you more about it next Satteday.—Yors truly,
 BILLY NUT.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

WE supplement our report published last week of the annual meeting of this Society by fuller details from the official journal of the Society.

After the routine proceedings of opening the meeting, the following honorary members were unanimously elected on the recommendation of the council:—Dr. W. H. Draper, the University, New York, and Dr. H. Vogel, the Industrial Museum, Berlin.

The HON. SECRETARY then read the Report (in our uext).

Captain ABNEY moved the adoption of the Report, which had received the careful consideration of the Council.

Mr. MAWDSLEY seconded the motion, which having been carried, a vote of thanks was unanimously passed to Lieutenant Darwin, R.E., the Honorary Secretary.

Mr. J. SPILLER (Treasurer) read the balance sheet, regarding which he observed that the sum total of it appeared to be that the Society had been living up to or even a little above its means. At the same time it must be taken into consideration by the members that they were occupying magnificent premises with the effect of bringing them a large increase in their numbers. There was a long list of new members, but these would not appear in the balance sheet until next year, when a much more favourable aspect would be presented. The amount for gas represented the consumption for two years, as some delay had occurred owing to the difficulty at arriving at an equitable agreement with the proprietors of the room. He might remark, with regard to the assets, that it was the opinion of the auditors that they were of a higher value than last year. This was owing to the diligence of the Council in scrutinizng the list of arrears, with the result that the outstanding debts had been considerably reduced. The amount standing under the head of subscriptions

also compared favourably with other years. The arrears had been looked up, and the total paid in was now £252 as compared with £223 in 1877, and £211 in 1876. He might also say that though the expenses connected with the *Journal* might seem high, this was due to several items which might properly be charged in the "general expenses."

The PRESIDENT, in moving that the balance sheet be adopted, said he thought it presented the affairs of the Society in by no means an unfavourable light.

Captain ABNEY seconded the adoption of the balance sheet. In moving a vote of thanks to Mr. Spiller, Captain Abney referred to the trouble that gentleman had taken with respect to his duties as Treasurer.

Mr. SEBASTIAN DAVIS, in seconding the motion, observed that he knew from experience the exertions required in connection with the office, and was quite sure that no one had discharged that office more efficiently than had Mr. Spiller.

A vote of thanks having been passed to the Auditors, The PRESIDENT observed that in future it was hoped that the decision with respect to the Progress Medal would be made known at the Annual Meeting. At present the Council was engaged in considering the award, and the decision would be shortly announced; and this was also the case in regard to the Paget Prize Medal. The Presentation Picture was in a very forward state, and in the course of the next ten days, if it met with the approval of the Council, it would be circulated among the members.

Colonel STUART WORTLEY then moved a vote of thanks to the President. Mr. Glaisher gave an immense amount of time and trouble to the Society's business, and he was quite sure that without his guidance the members would feel at sea. The President took care that no mistakes were made, while the prestige that was attached to the Society from its association with his honoured name could hardly be overrated.

Mr. W. BEDFORD having seconded the motion,

Mr. SPILLER put the vote to the meeting, and it was carried with acclamation.

The PRESIDENT, in reply, said he thanked the members as warmly as they had thanked him. He could assure them that no effort would be wanting on his part to advance the interests of the Society. He might say that he was now one of the oldest members of the Society, and had been associated with its fortunes both at King's College and at Conduit Street, and his list of attendances was, at all events, a guarantee of the interest he took in its welfare.

Mr. J. HARMER, of Arndel, then exhibited a new camera, by which repeated focussings could be made without the necessity of withdrawing the dark slide. Mr. Harmer read a paper on the subject (see page 86.)

Mr. YORK, as one who had had much experience in photographing animals, thought there were two objections to Mr. Harmer's camera. One was the noise made in moving the mirror. This he considered would be enough to frighten any animal. The other objection was the cap placed in front of the lens. Otherwise the arrangement was a very efficient one.

Mr. HARMER said the noise was due to his bad workmanship. If the camera was made by a professional workman, he did not think there would be any noise. With regard to the cap, it was the ordinary method of uncovering the lens, and he had not attempted any alteration in that respect.

After a vote of thanks had been passed to Mr. Harmer,

Captain ABNEY read a paper "On Silver Bromide Emulsion in Gelatins" (see page 88).

Mr. JOHN TALBOT LANE exhibited a printing-frame, which had attached to it an ingenious contrivance for vignetting.

Mr. W. BEDFORD then showed a new instantaneous shutter, and read some observations respecting it (see page 87).

Mr. HENRY then showed a camera in which the front board could be entirely removed from the dark slide, thus doing away with the annoyances arising from the use of a hinge. Mr. Henry's invention consisted of a strip of wood which was pressed against the shutter by means of a spring, and when the shutter was removed pressed against the frame of the dark slide, effectually preventing the admission of light.

The PRESIDENT, in closing the meeting, said, he had one favour to ask the members. The pictures which now adorned the walls would be removed before the next meeting, and he hoped the members would do all they could to supply their place with photographs, the larger the better. When the meetings were held at King's College photographs were always shown, and were productive of much useful and interesting conversation. Contributions of any kind will be greatly welcomed.

The meeting was then adjourned till the 11th of March.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The fourth ordinary meeting of this Society was held in 5, St. Andrew Square, on Wednesday evening, the 5th inst., JOHN LESSELS, Esq., President, in the chair.

Before commencing the business on the billet,

The CHAIRMAN begged to express his regret at the loss which the Society had sustained by the death of one of its members; he referred to Mr. Dallas, who had been connected with the Society for about ten years, and who during that time had taken considerable interest in the various operations. As a private friend, and brother elder in the same church, he had found him a warm-hearted man, and one it was always a pleasure to meet and have dealings with. His ability as a photographer was well-known. He had specially devoted his attention to the permanent processes for book illustration, and, being a teacher in the School of Design, it was not surprising that he had made the art capacities of photography his peculiar study. Mr. Lessels then moved that the Society send a message of sympathy to the widow and family of the deceased.

Mr. W. H. DAVIES seconded the motion, and in doing so referred to the late member as a dearly beloved friend, and as a man whom no man could know without loving.

The SECRETARY was then instructed to record the motion in the minutes, and send an extract to the widow.

Fourteen new members were then proposed, and unanimously admitted, viz.:—Messrs. Robert Wight, Councillor Doig, Aitken Dott, Robert Buist, William Downes, George Walters, Robert Denson, William McGregor, E. J. Craig-Christie, Rev. R. F. Colvin, Robert Hamilton, John R. Aucrum, John G. Wood, and W. T. Sutherland.

Dr. WILLIAM TAYLOR exhibited and described a new "Automatic Syphon," devised and constructed by himself. Dr. Taylor gave an amusing account of the cause of its origin. In his dining room he had a large slate-bottomed aquarium, which, from its position and construction, would not allow of the usual overflow passing through the bottom; and, in consequence of the irregular supply of water, it sometimes happened that the room was flooded, and various aquatic animals were discovered floundering on the carpet or tumbling down the stairs. This called forth a mild suggestion that it would be advisable to adopt some effective means to prevent the occurrence of such a mishap, and, making use of the blackboard, Dr. Taylor illustrated the various experiments tried, until, from the use of cranks and pulleys, the apparatus had culminated in the simplest of devices, which perfectly served its purpose. The practical working of the syphon gave great satisfaction to the members present.

The PRESIDENT expressed himself highly gratified with the invention, and was surprised that from its extreme simplicity it had not been thought of before.

Mr. W. T. BASHFORD said that he had seen the apparatus elsewhere, and was so impressed by its ingenuity, simplicity, and probable usefulness to the photographer, that he had asked Dr. Taylor to submit it to the Society. This Dr. Taylor at once most courteously consented to do. He had no doubt that many uses might be found for it.

Mr. LAURIE said that if he had possessed such an apparatus five years ago, it would have saved him much annoyance and expense; he greatly admired the thoroughly effective way in which it did what was required.

Mr. PRINGLE thought the ingenuity displayed most commendable, and that while it could not take the place of such an effective apparatus as a Moulton's washer, it would, nevertheless, be of incalculable service in many operations.

Mr. CRAIG-CHRISTIE, knowing the requirements in chemical manipulations, considered the apparatus invaluable; many people would have patented it, and by making the syphon public property Dr. Taylor had acted most liberally.

Mr. W. H. DAVIES considered that the admirable way in which Dr. Taylor had overcome the difficulties which led to this invention was worthy of all praise.

A cordial vote of thanks was passed to Dr. Taylor for his kindness in bringing the matter before the Society.

Mr. H. H. PILLANS referred to a communication which he had received from the Editor of the *St. Louis Practical Photographer*, and laid on the table a number of that journal, together with several examples of American portrait work as a supplement to an article therein, which had been sent to the Society by the Editor. The photographs were much admired.

Mr. W. H. DAVIES then proceeded to read a paper entitled "The Spirit of the Journals." He explained that owing to the

pressing claims on his time, he had been unable to give that attention to the subject that he would have wished, and further, he thought that such papers were rendered almost unnecessary, seeing that everything of value was recorded in the Almanacs, which were becoming more and more popular every year. Referring to Mr. J. T. Taylor, he said that that gentleman was due in a large measure the credit of instituting the Edinburgh Photographic Society, and it was no less owing to his energy combined with Mr. Warwick (the present Town Clerk of Glasgow) that the Society had attained its well-earned success. He (Mr. Davics) was sure Mr. Taylor carried along with him to his new sphere of labour the best wishes of the members.

Mr. Davics' paper called forth a good deal of discussion, in which Messrs. Lessels, Annan, Mathison, Turnbull, Craig-Christie, and Dr. Thomson, R.N., took part.

In the matter of heating the dark room Mr. Mathison said that in his experience with gelatine plates he had found the ordinary gas stove work satisfactory. Mr. Lessels considered a current of warm air more preferable. Dr. Taylor stated, from experience gained during the past severe winter, that he felt nothing could equal the spirit lamp for keeping up an uniform heat combined with purity of atmosphere. He recommended this in preference to every other method. Of course experience would determine the size of the lamp, or how many should be used to secure the desired temperature.

The following items were found in the "Question Box."

1. "What is the best dry process for an amateur to work who is going abroad?"

Mr. TURNBULL recommended the collodio-bromide process as being by far the most simple and certain.

The PRESIDENT considered Mr. Turnbull's own "Waverly Plates" to be the best that could be used. He could not conceive of anything more simple to manipulate, or more certain in results; and his experience had extended over all the well-known dry processes.

2. "Can any member give a simple formula for photographing on wood blocks for engraving?"

The Questioner was referred to a paper on this subject read before the Society some years ago by Mr. Alexander Nicol, and in which the whole process was clearly explained.

On a vote of thanks being given to the Chairman the meeting adjourned.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

The ordinary meeting of this Society was held at Bradford on the 3rd inst., Mr. JOHN HOWARTH in the chair.

After the minutes of the preceding meeting had been confirmed,

Mr. E. WORMALD read a paper "On Albumenizing Plates" (see page 87).

In reply to Mr. A. Sachs, as to the reason of Mr. Wormald's using such a large quantity of ammonia,

Mr. WORMALD said he considered that it acted as a solvent of the albumen, and gave, on the addition of the water, a solution of very uniform density, and very easy to work with. He further stated that he had frequently tested his bath, and had not found any symptoms of alkalinity. He had used baths for a very long time, and had not found any sensible depreciation. His baths were not very acid to commence with.

Mr. MORI said he had been informed by a friend that he found when he exceeded six drachms his bath soon got out of order and became alkaline. He could work a bath three times as long with a small quantity of ammonia in the albumen as he could if he exceeded the maximum six drachms. He (Mr. Mori) went on to say that if Mr. Wormald used an old ripe collodion it would contain a quantity of free iodine, and have a similar effect upon the bath as acidifying it, so far as neutralizing the effect of the ammonia went.

Mr. SACHS said he frequently used his albumen without the addition of ammonia. His opinion was that the use of ammonia was simply to confer keeping qualities upon the albumenous solution.

Mr. MORI remarked that age produced the same effect upon albumen as did the addition of ammonia. Fresh albumen could not well be used. It required keeping three or four days, until a slight decomposition had set up; then fresh albumen was added, when it would work well and coat the paper evenly.

Mr. E. PASSINGHAM said that he used six grains of the dried albumen to twenty ounces of water.

In reply to a question by Mr. John Smith,

Mr. WORMALD said he did not particularly attribute the cleanliness of his plates to the albumenizing, but he did claim for it certain cleanliness and a great tenacity in holding the film on the plate.

The thanks of the meeting were then passed to Mr. Wormald for his paper.

Mr. W. T. BURROW asked if any emulsion worker present had had any difficulty in keeping the film on the plates when previously albumenized. He had tried both old and new albumen.

Mr. J. SMITH and Mr. HOWARTH had found that edging the plate with some medium repellent of the water was the only method of obviating it.

The CHAIRMAN said that he had been troubled with transparent spots in plates which had been albumenized and kept for some time, and on examining the plates he found the spots were visible before coating, having the appearance of spots of moisture. He used a mixture of hydrochloric and sulphuric acids for cleaning the plates.

Mr. SMITH then suggested an explanation of the spots upon Mr. Howarth's plates. The surface of glass not being perfectly homogeneous, it was possible that a slight trace of acid might have been left in the pores of the glass which might attract moisture, sulphuric acid having a great affinity for water. Or if the plate were cleaned with nitric acid, and afterwards rinsed with ammonia, nitrate of ammonia would be formed, which being a very deliquescent salt would produce moisture. The same result would occur in the case of emulsion films; the film would become disintegrated and produce a transparent mark.

After a desultory conversation, the meeting adjourned.

Talk in the Studio.

THE PAGET PRIZE.—The following are the members of the Council of the Photographic Society appointed to serve on the Committee for the Paget Prize for Dry Plates:—Mr. V. Blanchard, Lieut. L. Darwin, Mr. S. T. Davis, Mr. P. Mawdsley, Colonel Wortley. Competitors are informed that we shall publish the address to which the plates are to be sent, probably in our next issue. In case the competition is a close one, it might be advisable to send for trial more than the minimum number of three dry plates.

PHOTOGRAPHY AT A BALL.—At a fancy dress-ball held at the Vestry Hall, Chelsea, on St. Valentine's Eve, Signor Lombardi had a large-sized Luxograph fitted up in the gallery of the ball-room, and it was worked under the supervision of the patentees, Messrs. Alder and Clark, who, during the evening and night till 4-13 the next morning, took over 120 full length cabinet negatives, using the gelatine plates of Messrs. Wratten and Wainwright, the exposure varying from two to seven seconds, thus evincing the practical utility of the Luxograph. During a period of three hours in the night, negatives were made at the rate of eighteen per hour, a feat impossible with wet collodion.

ENLARGEMENT BY ARTIFICIAL LIGHT.—The Autotype Company have just issued a circular referring to their enlargements, the excellence of which has always been acknowledged, but the delay in the production of which has been a serious source of trouble to their customers. They now announce that by the use of a brilliant artificial light, and some triumphs of optical skill in the shape of enormous condensers, they are enabled to expedite their operations very greatly, and turn out excellent enlargements in all weathers within a fortnight of order. The nature of the artificial light has not yet transpired.

THE JUDGE ON COLOURED PHOTOGRAPHS.—A correspondent forwards us the following cutting from a Brighton paper, remarking that the judge's observations are rather cutting from the town that boasts a photographer as alderman and ex-mayor. "In the course of hearing a claim by a photographer at the County Court, on Thursday, to recover for three coloured photographs, Judge Martineau confessed that he himself looked upon coloured photographs as the most atrocious things ever invented, as being disgraceful from an art point of view; but he had no doubt they had a market value, and that people paid extravagantly for them—far more than they would think of paying to artists, young artists, for real works of art, the result of true skill and brain work."

PHOTOGRAPHIC REVOLUTION.—*Funny Folks* has the following:—"The PHOTOGRAPHIC NEWS announces 'a revolution in the studio,' of which Mr. Hazard is the leader. He has, it seems

abolished the negative bath with a positive gain, and reduced twenty-minute sittings to two. With these advantages we feel justified in regarding him as a winning Hazard."

BALLOON PHOTOGRAPHY.—Mr. Woodbury writes to the *Times* as follows:—"Among the various uses to which photography has been applied, that of reconnoitring from a captive balloon has had the least attention paid to it, principally from the danger to the operator in making ascents over an enemy, and, until lately, owing to the want of a process for obtaining negatives of sufficient rapidity to overcome the motion of the balloon. Both these difficulties are now overcome: firstly, as it is now quite practicable to send up a small captive balloon holding the camera and sensitive plates, the exposures being effected by means of electricity through the cord holding the balloon and apparatus; and, secondly, by the late strides made in the rapidity of dry plates (those of Swan and others), enabling views to be obtained even when swinging the camera in the hand. Had our army at the Cape been provided with such an apparatus, the cost of which would not exceed that entailed in firing a single shot from one of our big guns, the number and position of the enemy might have been noted, and the great disaster possibly averted."

MAGIC LANTERN ENTERTAINMENT.—A correspondent forwards us a cutting from the *Guernsey News*, from which we make the following extract:—"We were much interested on Thursday evening in a visit to the military hospital, Fort George, where Sergeant Morrison, of the Army Hospital Corps, had provided a magic lantern entertainment for the inmates. There were also numerous visitors present. With a view to relieve the monotony of hospital life the sergeant has provided a first-class lantern at his own expense, which with a very large series of slides, principally photographs taken by himself in different parts of the world, he is able to afford a pleasant and profitable evening's entertainment. In preparing these slides, Sergeant Morrison has been greatly assisted by Mr. Howes, army scripture reader, of Jersey, who has very effectively coloured many of the photographs. We were particularly struck with the simplicity of the apparatus employed. Having for many years made entertainments of this kind a hobby, we know a little of the trouble they entail. It is one thing to sit for a couple of hours and enjoy the sight of beautiful scenes magnified upon a screen, but it is quite another thing to go through the ceremony of preparing gas and rigging up the intricate apparatus to prepare for the same. The latter is (or, at least, has been) an ordeal which but few have cared to encounter. So trying has it been to the patience, and so bitter have been the disappointments attending failures after all the pains, that every new method which science has from time to time introduced to give the best possible effect with the least possible risk, expense, and trouble, has been caught at eagerly and tried immediately. Of all these improvements, however, nothing has come under our notice hitherto which has so completely cleared the path from obstacles in providing such entertainments as that which we witnessed on Thursday evening. The apparatus used was a triplexicon lantern, the patent of W. C. Hughes, London." Then follows a description of this lantern, with eulogy of its merits.

To Correspondents.

H. F. W.—Over-exposure will produce thin negatives on gelatine emulsion plates. Using a stronger solution of pyro will give more intensity. From the example prints enclosed, however, we are inclined to think that diffused light is the chief source of your trouble. Remember that your dark-room must be, actinically, much darker for these plates than is required for wet collodion. More care in this respect, and a little less exposure, will, we think, remove your trouble.

J. B.—Chromotypes are carbon prints; but all carbon prints are not chromotypes. The latter are supposed to be produced upon a special tissue, and by a special method. A licence is required for the practice of the chromotype method, which has been fully described in our columns. For full information as to terms and cost of licence, write to the Autotype Company, the patentees. They will teach you the process if you take a licence.

W. D. BENNETT.—Captain Abney's Instruction Book is the most useful recent practical work on photography. M. Liebert's work is probably the most recent in French. Dr. Van Monckhoven's *Traité* is, probably, one of the best in the French language.

R. B. L.—The revolving albums were not made in leather, but of wood with glass in front. We know nothing of them beyond what we saw at the Exhibition.

TEN YEARS' SUBSCRIBER.—An emulsion plate may be a dry plate, or it may be worked in a moist state. The name dry plate simply is most commonly given to a plate prepared in a bath like wet collodion plates, washed, treated with a "preservative," and dried. An emulsion consists of a vehicle like collodion or gelatine in which the sensitive silver salts are very finely divided, and held in suspension, forming an emulsion. 2. A properly produced dry plate should be thin and transparent enough to print as quickly as a wet plate. The negatives of which you complain are probably a little fogged; a little too much light in the dark room will produce this condition.

HUGH WALKER.—Your best course with the facilities you possess is to produce first a transparency from your small negative, and from that an enlarged negative. There are various modes of producing transparencies. If you are familiar with any of them, use it; but if not, try the method described by Mr. Blanchard on p. 33 of our last YEAR-BOOK. In any case, take care that the transparency is clean and well defined. Then from this transparency make an enlarged negative. If your quarter-plate lens have an equivalent focus of seven inches, which will be somewhere near its mark, and you wish to enlarge to four times the size of the original, your camera will require extending to thirty-five inches, so as to give this distance between lens and sensitive plate; and the transparency must be placed $8\frac{1}{2}$ inches in front of the lens. It is possible to produce an enlargement direct upon paper, as you wish; but it is not easy to produce a good enlargement so. In such a case you must use the camera as a magic lantern, and use a strong artificial light. Expose the sensitive paper wet, and develop with gallic acid. You can purchase iodized paper ready for silvering of Mr. Solomon, who also sends instructions for its use. The smallest sized condenser found suitable for use with a solar camera is one of 9 inches diameter, and 18 inches focus. Such cameras require direct sunshine. We know nothing of the firm you mention.

ARTIFICIAL LIGHT.—You will find some recipes for pyrotechnic compounds in the present issue. We do not remember the precise compound which was used by Mr. Moule. It was a very brilliant light, something of the nature of the Bengal light. Moule's patent was for the lamp, not for the fire.

ALBION ALBUMENIZING COMPANY.—We have received a letter from this Company expressing disapproval of the answer given to "W. W." in a recent issue in reply to his enquiry for their address. The case is very simple. We have received during the last month or two several enquiries as to the commercial use of Mr. Willis' platinum process. In reply we referred enquirers to the Albion Albumenizing Company, who were, and, as far as we know, are still, agents for the process. We next received some enquiries for the address of the Company, one correspondent saying he had sent to their address as he found it advertised, and had received no answer. In order to reply accurately, we searched for their most recent advertisement, expecting to find it in the YEAR-BOOK, but not finding it, we answered that we did not know it, and expressed a fear, which our correspondent had suggested by asking us if anything had happened, that such might be the case, the thing happening, being in our mind illness, death, removal, or change in its varied forms. Our correspondents think our answer was not couched in proper language, and ask for an apology. If they will tell us the ground of offence, we will apologize with pleasure. In the meantime we are glad to hear from them, and should have been glad to insert their address now, but their communication does not help us to do so, as the printed address on their note, "90, West Regent Street, Glasgow," is struck out with a pen, and the only address remaining is "Works, Hammersmith, London, W."

ONE IN A FIX.—Very shortly. The first time we can properly spare space.

OSCAR RAETHEL.—There are two photographic societies in London: the Photographic Society of Great Britain, 5, Pall Mall East; and the South London Photographic Society, the meetings of which are held in the rooms of the Society of Arts, John Street, Adelphi. We shall have pleasure in receiving the sample of collodio-chloride paper of which you speak.

BUTTERFLY.—The burnt sienna backing would doubtless help you. On the question of exposure it is absolutely impossible to speak with any approach to accuracy or precision, the terms "good light," "bad light," "well-lighted," &c., being so purely relative. Speaking generally, we should think ten minutes a very long exposure.

CHARLES WHITE.—The subject of blisters in albumenized prints has been much discussed, and many remedies proposed for which we must refer you to back numbers. Immersing the print in strong methylated spirit before fixing is found by many to answer. Longer floating on the silver bath is often a remedy.

W. COBB sends us a letter calling our attention to the fact that he announced some time ago, at the South London Society, that he had abandoned wet plates for studio work. He sends us some charming results from dry plates. His letter shall appear in our next.

Several Correspondents in our next.

The Photographic News, February 28, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AND PUBLISHERS.—ANOTHER PROCESS OF PHOTOGRAPHING IN COLOURS.—PHOTOGRAPHY AND BALLOONING.—THE LATE MR. LE NEVE FOSTER.

Photography and Publishers.—Photography is made use of by publishers in an important manner as a means of reproducing woodcuts for advertising purposes. We had in our hands recently a little pamphlet on every leaf of which was a picture of some sort, reduced by means of photography from the original work. In this case the publisher desired to advertise a dozen of his illustrated books, and no better means of doing this could hardly be imagined. The style and value of the engravings in the book could at once be judged from the reproduced specimens, which, moreover, had the effect of interesting the casual observer far more than any other advertisement could have done. Indeed, the publisher, instead of producing an uninteresting pamphlet of advertisements which few would be tempted to peruse, had produced a little picture book that one was loth to throw away. His pictures, big or small, had all been reproduced of such dimensions as to suit the advertising pamphlet, and the consequence was, a result was produced that could not fail to please. One only wonders, in looking at such things, that more attempts are not made in the same direction, not only for advertising purposes, but for multiplying editions. Type may be reproduced in type, in the same way as a printed woodcut will yield another eligible suitable for printing from again. If type is good and clear, and printed upon white paper, the production of other types, perhaps a little smaller, presents no difficulty, and it is surprising that photography is not at times employed upon such work. If there are plans or sketches with the letterpress, the camera at once affords the easiest mode of reproduction; the only precautions to be taken when the photo-types are produced being, that proper paper—with the finest possible surface—is used for printing. In the reproduction of music and work of that stamp, the lithographic or zincographic methods are more suitable, and the work is then simpler still. There must be a vast deal of old and valuable music that might be copied with advantage in this way with the camera, and the latter would at once afford the means of producing several editions of various sizes. In the case of part songs, where the singers have to hold their music in their hands and carry it about with them, it would be a great boon to be provided with small sheets of music; and if these were reduced by photography from larger editions, there would be no doubt about the clearness of them. We can only suppose that it takes some time to open the eyes of our publishers to the facilities of photography, and to the aid the camera can lend them in their work.

Another Process of Photographing in Colours.—Another process of photographing in colours has been brought forward. These methods are now getting rather numerous; and yet, somehow, we do not get on so well as we might with the taking of negatives with colours, or rather of producing prints from negatives that have all the varied tints of the original. The last process is heralded in *Truth* in the usual manner, and is of course to "revolutionise photography." We are unacquainted with the merits of the new French invention, but, having known so many methods of colour-photography, one naturally gets sceptical about them. As a rule, such novelties are brought before the public with a good deal of talk about patents, and about the work of early investigators, and the author of the process seeks to show that he has triumphed over all, and has now attained the end everybody has been striving to reach. That is what the public are told. To photographers, photographic societies, and photographic journals, another story is usually unfolded. They are to understand that it is not the securing of direct photographs in colours that have been achieved, and must not be led away to suppose so, like the foolish and

ignorant public who read the first manifesto. To them the method is very simply explained, and the inventor would be the last person in the world to attempt deception. But, for all that, there is to be seen at public and private exhibitions, from time to time, coloured work which visitors have put before them as photo-chromes, chromic-photographs, &c. Half a dozen processes at the very least which have been brought forward of late are simply based on the principle of applying colours behind the photographic film. When Woodburytype was first published to the world, we remember seeing "coloured photographs" produced in this manner, a transparent gelatine film being put over a roughly coloured surface; and since then the same principle has been applied in various ways with carbon and silver transparencies. The dodges are in themselves more or less clever, and sometimes produce very charming results, but to pretend for one moment that photography in colours has anything to do with such productions is of course simply absurd.

Photography and Ballooning.—It seems well-nigh settled that ballooning is to become an institution of the British Army, and we are to have one of the companies of Royal Engineers equipped as a balloon corps. The main duties in connection with such a service will be in connection with reconnoitring the enemy, or surveying a hostile country, and in carrying out such duties the photographer should be able to render assistance. The great difficulty in balloon photography must always be to overcome the gyrations and general unsteadiness of the machine. In the case of the great Paris balloon there was less reason to fear defects from this cause, since the balloon was steadied as far as possible by ropes from its girdle. In ordinary balloons this somewhat complicated arrangement could scarcely be expected, and hence the operations of photography are beset with far more difficulty than was the case in the large Exhibition balloon. However, M. Nadar, of Paris, in some attempts undertaken seven or eight years ago, did succeed very well in efforts to secure photographs under the ordinary conditions of the aeronaut, and now that we are in possession of plates more sensitive than ever, there should be less difficulty still in the matter of military balloon-photography: In bush-covered country, such as Zululand, there would be plenty of scope for ballooning, and now that there seems no difficulty about making hydrogen gas on the field, or conveying it thither in a compressed form, Government may be induced to give an equipment of the kind a fair trial.

The Late Mr. le Neve Foster.—Mr. Peter le Neve Foster, the secretary of the Society of Arts, one of the earliest members of the Photographic Society, and for many years one of the council of that body, died suddenly last week at his residence. Gout of the heart is ascribed as the immediate cause of his death, for Mr. Foster was in enjoyment of good health at the time, and we ourselves saw him chatting with some friends under the Regent Street Piazza within twenty-four hours of the occurrence. The deceased gentleman resided at Wandsworth, and he left the Society of Arts office on the 20th inst. in his usual health and spirits. He walked from the station, it appears, which was his usual custom, and none of his family noticed any alteration in him. However, while he was by himself for a few minutes, he was suddenly seized with an attack which carried him off in a few minutes. In fact, his daughter, coming into the room, found that he had fallen back from his chair dead. Mr. Foster for many years has been the life and soul of the Society of Arts, and his death coming so close upon that of Mr. Davenport, the late energetic financial officer of the Society, will be a sad blow to that body. These two officers worked hand in hand for a long time, and the vigour and life of the Society was due as much to them as to the lectures and meetings with which the Society is associated. Mr. Foster, we believe, was on the eve of retiring from the secretaryship at the time of his death, and a subscription had been set on foot to raise a sum of money to purchase a suitable testimonial on retirement. He was a Master of Arts, and barrister-at-law.

ON THE CAUSES OF INSOLUBILITY IN CARBON TISSUE.

BY E. BRIGHTMAN.*

ALL workers in carbon printing at times experience the annoyance caused by batches of the sensitized tissue becoming partly or entirely insoluble. The subject having been brought before us at one of our meetings in the form of a query for our question-box, and no satisfactory solution having been given, I have been making a few experiments with a view to throwing some light upon the matter.

The experiments I have made, though they do not point to any one sole cause of insolubility, lead to a knowledge of some of the causes, and knowing the causes may, at any rate, teach us what to avoid.

It is usually asserted that slow drying of the tissue, and moisture remaining in the gelatine after sensitizing, is the sole cause of partial or total insolubility. This I certainly cannot admit, for I have had batches of tissue rapidly dried and kept in a perfectly dry atmosphere which have become insoluble in the course of a few hours. On the other hand, tissue which has been some day or two in drying has remained perfectly soluble, and given good and satisfactory prints. Doubtless, moisture in the film will cause it more readily to absorb injurious fumes, and thus tend to insolubility; but, given a perfectly pure atmosphere, I do not consider that moisture *per se* can in any way cause insolubility. I am inclined to think that the secret of keeping the sensitized tissue soluble is to exclude the air as far as possible, and to take care the air in which the tissue is kept should be perfectly pure and uncontaminated with fumes of all sorts. To test what external causes tend to insolubility, I have subjected pieces of sensitized tissue to the following gases, fumes, and vapours:—Ammonia, carbonic acid, acetic acid, sulphuric acid, ether, alcohol, sulphurous acid, phosphoric acid, iodine, oxygen, carburetted hydrogen, carbonic acid, collodion vapour, with the following results:—

Ammonia increases the solubility of the tissue; pieces of tissue exposed to the vapour of ammonia and also to fumes from the ammonia carbonate dissolved at a lower temperature than other tissue.

Carbonic acid causes perfect insolubility.

Nitric acid causes perfect insolubility, water at boiling point having no effect whatever upon the gelatine.

Phosphoric acid produced partial insolubility, and appears to act irregularly, the tissue being rendered partly insoluble in patches.

Finding that ammonia tended to increase solubility, and that carbonic, nitric, and phosphoric acid produced insolubility, I was led to the conclusion that alkalies were favourable, and acids opposed, to solubility, and was therefore greatly surprised, on testing the sample of tissue which was exposed to the fumes of acetic acid, to find that it was more soluble than the normal tissue, and dissolved at a lower temperature than any of the other samples.

Sulphuric acid appeared to have no effect upon the solubility of the tissue, other than might be expected to arise from the gelatine becoming very dry and brittle in consequence of the well-known property sulphuric acid has of absorbing moisture, the highly dried tissue naturally dissolving less readily than those containing more moisture.

Fumes of collodion appear to produce partial insolubility. In order to test whether this was caused by the alcohol and ether or by the iodine, I subjected portions of tissue to the vapour of ether and alcohol alone, without any effect on the solubility. We may therefore conclude that in this case iodine was the cause of insolubility.

Oxygen appears to have a slight tendency to produce insolubility, but as the oxygen was not carefully purified, it probably contained traces of chlorine; this experiment, therefore, cannot be accepted as satisfactory.

Carburetted hydrogen produces slight insolubility; car-

bonic acid gas apparently no effect; fumes from burning house gas, decided insolubility.

The result of these experiments shows that while some gases, vapours, and fumes are harmless, others are decidedly injurious; therefore sensitized tissue should be kept with the air excluded, as can be done by placing the sheets between stout plates of glass under pressure in an ordinary screw-back printing-frame.

As ammonia and acetic acid both tend to solubility, I intend to try whether keeping the tissue between sheets of paper impregnated with their fumes will assist in preserving the paper in a soluble state for a lengthened time.

The result of the trials shall be communicated at a future meeting.

PATENTS IN CONNECTION WITH PHOTOGRAPHY BY ARTIFICIAL LIGHT.

BY W. J. CHADWICK.*

IT was my intention to have given you this evening a more exhaustive communication on photography by artificial light in conjunction with some experiments in which our friend, Mr. Garside, had kindly offered his assistance; but as I fear we have quite as much before us as we shall be able to get through to-night, I will simply give you a few facts and dates in connection with patents referring to that subject.

The first patent I can find recorded on this subject was granted to Antonie Jean Francois Claudet, in the year 1841, No. 9193, and is styled "Certain Improvements or Means of, and Apparatus for, Obtaining Images or Representations of Nature or Art." On page 3 he mentioned artificial light for taking photographic portraits by night. The artificial light is produced by the combustion of coals promoted by oxygen gas; and on page 3, line 33, he states that a reflecting mirror of a concave form must be adapted behind the light, and the light placed in the axis of the reflecting mirror to be used in photography by artificial light.

The next patent was granted to Pierre Bernardet de Lucenay in 1852, No. 575, about eleven years after Claudet's, entitled "The Production of Photographic Images by Artificial Light." On page 1, line 10, he states that the lights must be parallel or diffused. It is rendered parallel by placing the light in the focus of a parabolic mirror. On page 2, line 4: "The light is to be rendered diffused for portraits. In this case the interposition of blue cobalt glass will be required." On page 3, line 8, the light is said to be produced by an electric battery, or by the combustion of pyrotechnic compositions. On page 4, line 16 to 25, he makes use of unpolished glass on paper, and where the electric light is employed, it will be convenient to intercept that light by means of the unpolished glass or paper, and so render the light more diffused when thrown on the object to be photographed. You will see that in this patent artificial light and the use of the reflector are not new, as M. Claudet used them eleven years previously.

Next we have the patent of John Moule, 1857, No. 478, and styled "Improved Apparatus to be used in Burning Pyrotechnic Compositions or Preparations for Producing Artificial Light of Various Colours." From this patent it will be seen that a lantern is to be used for burning the pyrotechnic composition, with a pipe or tube to carry away the vapours given out by the combustion of the compounds, and so rendering it applicable to photographic purposes in rooms or close buildings. On page 2, line 24, is mentioned that coloured glass will be found exceedingly useful for photographic purposes. Line 26: Reflectors may also be adapted to the apparatus for the purpose of collecting and throwing the rays of light in any particular direction. You will find that the use of pyrotechnic compositions and coloured

* Read before the Bristol and West of England Amateur Photographic Association.

* Read before the Manchester Photographic Society.

glass are not new in this patent, as the same were patented by De Luceay.

We next come to the patent of Henry Vander Weyde, 1878, No. 446, entitled "An Improvement in Illuminating Objects to be Photographed, and the Interior of Public and other Buildings." On page 1, line 14, is stated that "the invention consists in the employment, in combination with the electric or other artificial light, of a parabolic or other concave reflector of comparatively large size, in the focus of which the light is placed, and a shield or screen of opaque or semi-transparent material placed on the opposite side of the light to the reflector." Now what is not new in this patent is the use of the electric light, screens before the light, and reflector, the above having all been previously patented by Dr. Lucenay, Claudet, and Moule.

The next patent is that of Messrs. George Edward Alder and John Archer Clarke, granted in 1878, No. 1442, and entitled "Improvements in the Means and Appliances for Producing Powerful Artificial Light for Photographic and other Purposes." On page 2, line 15, it is stated that any of the well known actinic artificial lights may be used—by preference, the pyrotechnic; at line 21, a reflector is mentioned of a suitable size—by preference one of four or five feet diameter; at line 24, in conjunction with the reflector a semi-transparent screen or screen is used between the source of light and the objects to be photographed, so as to disperse or diffuse the light; at line 36, it is said that in practice it is often found desirable to subdue the principal light by blue tinted glasses in front of it; at line 38, we find that when either pyrotechnic composition or magnesium is employed, a lantern of glass must be used, with a chimney to carry away the fumes. Now what is not new in this patent is the use of pyrotechnic composition; the use of a lantern for burning composition; the use of a reflector; the use of a screen in combination with the reflector to diffuse the light; and the use of tinted glass and the chimney or pipe to carry away the fumes of the burning combustions; the above having been patented by Claudet, De Lucenay, Moule, and Vander Weyde.

From what I have said you will see that there is very little, if anything, new in photographing by artificial light, and that it is free to the world in the form of electric and pyrotechnic lights; the use of lamps, with or without chimneys or flues; the use of reflectors, parabolic or concave; and with blue or tinted glass, or other medium for the light to pass through.

AN EMPLOYER'S EXPERIENCE OF OPERATORS

THE time was, in years long since past, when a common reproach hurled against photography as a profession, was to the effect that it was the general refuge of those who had failed in all other trades and professions—the "needy villain's general home!" In the present day, almost every operator has had some training or apprenticeship to his profession, which fits him for its practice. An employer, writing in the *St. Louis Practical Photographer*, is puzzled, in looking through advertisements, to find so many "first-class operators" wanting engagements, and so few of any degree of excellence to be found when wanted. Here are some of his experiences with operators engaged on "the tramp."

"My last applicant, only a few days since, had only worked about a year, and when I asked him what his formula was for toning, he says, 'Which?' I said, 'What do you use in your toning solution to get the best results?' 'Oh,' he says, 'I use gold to tone with; I think it is best.' 'But,' I said, 'what do you use with it—how do you mix it up, and how do you use it?' 'Well,' he says, 'I can't just exactly tell now, but I think we use some kind of soda in it; but if you want me to

work for you I can send and get the recipes from my brother, that tells just how to do it in fine style.'

"Shades of Daguerre! Claims to be a practical printer and toner, and yet must wait until he could get his recipes before he could do anything, and three years' experience at that!

"Then I showed this gentleman my photographic publications, that have been accumulating for years—more than he could lift—all full of formulas, instruction, advice, &c., and his eyes just protruded right out of their sockets, and he candidly confessed that 'he never knew that there was any other photo. publication except *Anthony's Bulletin*, and he had not seen many numbers of that.'

"Now, perhaps, it would not be out of place to give you some of my experience with some of the operators that have sought employment with me; for I am so situated that I am obliged to have a helper under the skylight. I will say just here, that I have had a good number of men in my employ that were both artists and gentlemen, while others have proved a fearful failure on my hands.

"At one time, some eight years ago, I was in want of an operator, and one day, while busy under the skylight, an ungainly-looking specimen of humanity presented himself and asked for a situation. As soon as I was at liberty, I looked him over. One thing certain, he had no beauty to recommend him. He had tawny-white and very long hair, calico eyebrows, a mouth that looked as if he had never said but one word, and that was 'ker-chug;' and feet! Great Sampson, what feet! All I can say about those feet is that they were just immense, and I don't think even to this day he is able to take care of them alone. But I needed help, and must have it; so I engaged him at once, big feet and all. So the next morning Mr. Slouch went to work. He silvered the paper for the day's printing, and when he got through he broke a sixteen by twenty tray all to smithers—he set it up to drain on the floor in the dark room, and then tramped those big feet into it some way, and of course the tray had to suffer.

"The second day Mr. Slouch got along very well till about four o'clock, with one exception; he undertook to make some ferrotypes for a customer, and instead of flowing the plate with collodion, he used varnish; of course he could not develop up an image, so he went to doctoring the bath, and what he put into it never will be known, but it never made a picture after that. About four o'clock he wheeled the posing-chair around to the stove, and then elevated those gigantic feet to the top of it; but whether the feet were too heavy, or the stove sheered off in actual disgust, I am not able to tell; but one thing I do know: I heard a most terrible clatter, and supposing that the man in the moon had lost his hold, and fell down through my skylight, I hastened into the room. What a sight met my gaze! Mr. Slouch sprawled out in one direction, the posing-chair in another, and the stove lying around kind of promiscuously like, the ashes flying, the carpet burning, and the smoke filling the room to suffocation. After setting things to rights again, I asked for an explanation from Mr. Slouch. All he could say was, that he 'kinder guessed he must have got to sleep somehow.' I was getting somewhat discouraged with my operator, but thinking of the old adage, 'Wait; bad beginnings makes good endings,' I decided to try him a little longer.

"The next day, about the first thing he did to distinguish himself, and to show his artistic skill, was to sit down on a beautiful and delicate posing stand, and it being a very delicate affair, he continued to sit down until he reached the floor, which he did with a vengeance that always accompanies the meeting of two solid bodies. Ilypo and Iron! but I was getting out of all patience; but I had orders to drive me for over a month at least, and I must have help of some kind; so he was set to silver the paper, which he did after a fashion, and I began to take courage again. But

alas! for human expectations. After pouring the bath into the bottle again (there was about three quarts of it), he had to set it in the sun. To do this he must go through the parlour, as I had a special place for it on the porch outside. As he entered the door something happened to those feet. What it was I never knew; but the bottle struck a marble-top table, and divided itself forthwith. The bath solution came down like a miniature Niagara, and deluged the carpet, the walls, and everything around it, while Mr. Slouch lay upon the floor in terrible combat with those feet. I picked out a few choice words from my vocabulary and made him a present of them, and advised him to run a threshing machine for about three months, and run it all the time on those feet, and perhaps in that time he would be able to get them where he could manage them.

"Not long after this experience another artist made his appearance, seeking a situation. His name was Wm. Rummy. He claimed to be a first-class operator. He had worked in all or most of the galleries of any note from New York to San Francisco. He was out with Duke Alexis on the plains, and made views during the big buffalo hunt. He had recommendations for work from artists that I know. He was intelligent, good-looking, knew what he was about, but had a very seedy look, knees and elbows out; in fact, too shabby to appear in the role of an artist in a genteel place. He had been used to getting fifty dollars per week, but would work for me for twenty-five dollars per week. I told him his appearance did not indicate a fifty dollar a week salary, and there was one conclusion I would be obliged to form concerning him, and he admitted it. He was sorry for it, but drink had wrecked him. But he had sworn off; he would start new if I would employ him; so I engaged him. He was all he advertised, a true artist, a genial, warm-hearted gentleman, a first-class business man for three months (and if his eye should happen to fall on these lines he can see that I appreciate those three months of his manhood to-day as much as I did then), and then there came a fall. He gave way to drink so, that he would come to the skylight so drunk that he could hardly stand. At last I discharged him. He got out of money, then he sobered up and came back and worked a few days, then went on a spree while the money lasted. But at last I found that he used up two quarts of alcohol, which was more than I could afford, so I bid good-bye to Mr. Rummy.

"But, after all, I don't know as I ever had a worse nuisance around me in my life than one Frenchman that I employed once, by the name of Mr. Dandic. He was neat as wax, wore kid gloves, stove-pipe hat, broad-cloth coat, had a very fair stock of photographic knowledge, and self-conceit enough to supply all the heathen Chinese this side of sunrise, and every lady that came to the gallery for a sitting, whether a maiden of sweet sixteen, or the grandmother of sixty, fell irrevocably in love with Mr. Dandic; that is, if you let him tell it, and he was always telling it; in fact, the time spent in polishing up and beautifying himself, and talking fool to ladies, and then boasting of it afterwards, used up all his time. Even in the middle of the day, when we were crowded with sitters, he would talk his senseless twaddle with some young girls, who only wanted to see how big a fool he would make of himself, while good paying customers were waiting. And when there was any work to be done, like cleaning, sweeping, washing plates, getting water or wood, he would take money from my drawer to pay some boy to do it, while he waxed his moustache, parted his hair in the middle, or made a fool of himself generally. I had to call him a bad lot, and let him break hearts under some other skylight than mine.

"But, to conclude, I don't think, as a rule, that good competent operators are apt to go begging for a place. There is a class of men who fifteen years ago were in high feather. They are those mechanical operators. In those

days you could find them in every little town; either in some garret, or in a car, or portable shanty, they could hold their own with the rest. But photography has advanced with giant strides, and to-day it takes an artist to make a photograph that will bear comparison with the work that is sent out by photographers of the world; and the consequence is, that machine workers have lost their patronage, and have been obliged to shut up their shanties; for even pictures at the ten per cent. per doz. price fail to bring the crowd of customers they wish for. So, of course, there are hundreds of them lying around loose, or on the tramp looking for a job; and as they are not wanting in cheek, and you may be wanting some help, the chances are that you will be employing one soon, so I want to give you a little advice—*i.e.*, beware of the two extremes: never employ a slouch nor a dandy."

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

IN the following chapter the author describes the behaviour of gum and dextrine with the chromates.

Gum—under which denomination are included both *gum arabic* and *gum senegal*—behaves with potassium bichromate more like gelatine than sugar. This substance, which consists essentially of arabin or arabic acid combined with calcium and potassium, is soluble in its own weight of water, but when heated to from 120° to 130° C. it is converted into a salt of metarabin, which is insoluble in water. When a solution of gum is acidulated with hydrochloric acid, and treated with alcohol, arabin is precipitated as a white amorphous powder, which, so long as it is kept moist, is soluble in cold water; but when once dried it is converted into metarabin, an isomeric modification of the same substance, which merely swells up in water, and refuses to dissolve, though if it be treated with alkalies it dissolves rapidly, forming arabates.

A dilute solution of gum decomposes when exposed to the air, and turns sour after only a few days. In such a condition, though it may still possess adhesive power, it is useless for photographic purposes; but the addition of a little quinine or carbolic acid will check the decomposition. Gum is not precipitated by chrome-alm, but forms merely a green liquid, and when this is evaporated to dryness, the residue is no longer soluble in water. In fact, so soon as the solution is allowed to dry it becomes insoluble; this, in the opinion of the author, is due to the formation of chromium metarabate. The insoluble mixture of chrome-alm and gum resists for a considerable time the action of strong alkalies and of hydrochloric acid.

Like chromated gelatine, the mixture of gum and potassium bichromates is most sensitive when in a dry state; when exposed, it turns brown, and becomes insoluble in those parts that have been acted on by light. When in solution it may be kept for days exposed to diffused daylight without undergoing any change; but when dried it will become insoluble after a time, even in the dark; in the latter observation the author is corroborated by the experience of Wharton Simpson. If, however, a little carbolic acid be added to the same mixture, saturated to excess with ammonia, it will keep for a long time in the dark before any symptoms of insolubility make their appearance, while it does not seem to lose at all in respect of sensitiveness.

In former times, carbon photographs were often produced in chromated gum, but the substance could only be used for direct carbon printing where the pictures possessed no half-tones. Carbon tissue prepared with gum must be sensitized by floating the reverse side only on the chromate bath, or the film will be dissolved. For photo-

* Continued from page 41.

lithographic transfer paper, and for photo-lithography generally, as well as for photo-zincography, gum was also at one time used, but was soon superseded by gelatine and albumen. In the carbon process, gelatine is superior to gum, in rendering the requisite softness and half-tones of the picture, and in photo-lithography chromated albumen is to be preferred to chromated gum, both for the stone and for the transfer paper. A chromated mixture of gum and dextrine is sometimes used in photographic etching on metal, and in printing fabrics chromated dextrine is used on account of its being rendered insoluble by the action of light. There is one property of gum which renders its use in photography still valuable—the property, namely, that when mixed with a chromate and exposed to light it loses its hygroscopic qualities; it is on this account preferably employed in the dusting-on process, but always in combination with other highly hygroscopic substances, such as cane or grape sugar, treacle, honey, or glycerine.

The image on a film of chromated gum is destroyed by the action of the caustic alkalis, particularly when the solution of the latter is heated. An image on chromated gum develops completely in cold water, and in this respect the substance has a decided advantage over gelatine; if the development works too slowly, the addition of one or two per cent. soda to the developing water will expedite the action. Calcium chloride also has a distinctive action on the image on the chromated gum. Like gelatine, the gum film is most sensitive when it contains as much potassium bichromate as possible, up to the point of the latter's crystallizing out. According to the experience of the author, a carbon paper prepared with gum requires from five to ten times as long an exposure as one prepared with gelatine. He also found that chromated sugar is more sensitive than chromated gum, and recommends, therefore, the addition of sugar to the gum as an accelerator.

Gelatine has a peculiar action on gum; if gum be added to gelatine, and the mixture sensitized with ammoniacal potassium bichromate, the behaviour of the latter substance is very little altered by the addition of the former. Its solubility in hot water is somewhat increased, and to obtain the same degree of insolubility for the image as with pure gelatine the exposure must be longer. But if the mixture be acidulated with acetic acid, the film after exposure and desiccation is less soluble than one consisting of chromated gelatine only with acetic acid. Gum therefore renders an acid solution of gelatine less soluble, and the reason for this is believed by the author to be that gluten and arabic acid form a compound soluble only with difficulty. Borax thickens a gelatine solution, and the alkaline reaction of the same substance tends to render the chromated gelatine more insoluble. Calcium nitrate gives to gum* an enormous power of adhesiveness.

In order to be able to follow completely the course of the action of light on a mixture of gum and potassium bichromate, the author undertook the following analysis. He first prepared pure arabin by precipitating it from a solution of gum by means of hydrochloric acid and alcohol. By the addition of about twelve parts by weight of caustic potash in water to 100 parts by weight of this arabin, he obtained the potassium arabate, the accepted formula for which is $3(C_{12}H_{20}O_{10})_2K_2O$. The solution was then evaporated to dryness, and the salt submitted to combustion; the residue was found to contain 10-13 per cent. of potash, which corresponds very closely with the amount as given by the above formula.

The solution of this potassium arabate was then mixed with potassium bichromate. At a temperature of 100° C. the mixture soon turned green, and after being dried it became perfectly insoluble; it therefore became neces-

sary to prepare a film of the substance, and to dry it at the ordinary temperature. This film was then exposed to light for several weeks, until it had assumed a deep bronze colour; it was then digested first in cold, and then in hot water, and lastly, to remove all traces of chromic acid, boiled in a solution of ammonia. The whole mass was then dried at 120° to 130° C., and submitted to ultimate analysis. The result gave—

Carbon...	37.41
Hydrogen	5.63
Chromium oxide	5.76
Potash(K ₂ O)	9.30

The ash left in the porcelain boat contained potassium chromate and carbonate, with some undecomposed chromium oxide. This residue was well washed, and dissolved in hydrochloric acid; the carbonic anhydride that came off being conducted into a potash bulb, and its amount determined in the usual way, its amount was added to that of the carbonic anhydride obtained from the combustion tube. The undissolved chromium oxide was collected on a filter, and the chromic acid in the filtrate was reduced to chromium oxide by alcohol, and precipitated by ammonia. After the oxide had been filtered out, the solution of potassium chloride was evaporated to dryness, and weighed.

Neglecting the mineral compounds, the analysis of the organic substance gave the following result: carbon, 44.04; hydrogen, 6.63. According to the formula $C_6H_{10}O_5$ it should have been carbon, 44.44; hydrogen, 6.17. The composition, therefore, of the insoluble chromate gum, after exposure, agrees very closely with that of anhydrous arabin, and we may assume that the photographic image is formed of arabate (or, more probably, metarabate) of chromium and potassium. In this case, also, we see that the insoluble image is not formed by an oxidised organic substance, but by the combination of an unaltered organic body—arabin with chromium oxide.

Dextrine, or British gum, has often been substituted for gum arabic; for it equally turns brown when mixed with potassium bichromate and exposed to light, and also loses its hygroscopic properties. Chromated dextrine, however, only loses its solubility after weeks of exposure, and even when browned is still soluble in cold water. In these respects it differs from gum arabic, and is more like sugar. Dextrine is also used for the dusting-on process, when it is mixed with sugar and other similar substances, but the use of gum arabic is perhaps preferable; it is also employed in photo-lithography. When advantage is taken of its hygroscopic qualities, dextrine may, with effect, be substituted for gum arabic, but where the process depends on the insolubility of the exposed parts, dextrine cannot at all replace gum.

Gum tragacanth, when chromated, is quite as sensitive as gum arabic, but its great insolubility in water makes it useless for photographic purposes. It consists to the extent of more than one half of bassorin (which swells up, but is nearly insoluble in water), and contains only about fifty per cent. of soluble arabin. Mixed with potassium bichromate, and exposed to the light, gum tragacanth gives a brown image, but the parts not acted on only swell up in hot water, and refuse to dissolve. The author attempted to develop images of this kind by means of hot water acidulated with dilute sulphuric and hydrochloric acid, with only a partially successful result. If the development with acid be continued too long, the parts that have been affected by light will also give way. For these reasons gum tragacanth is not adapted for use in chromate-photography; it may, perhaps, be of service in the colotype, but certainly not in the carbon process.

(To be continued.)

* A mixture of this kind is used as a vegetable glue or cement.

DRY PLATES AN AID TO ARTISTIC PORTRAITURE.

THAT the complete and facile mastery of technical conditions may be an important aid to the production of artistic results few will doubt. Whilst the mind is harassed by technical considerations and doubts as to the best mechanical and chemical means to a desired end, there is little opportunity for carrying out purely artistic aims. Or if the purely artistic aims entirely possess the mind, the technical results must often fail. We well remember the comical distress with which poor Rejlander would hold up a spoiled negative embodying some charming art conception, bewailing the fact that whilst developing, and entirely engrossed in examining the progress of his artistic thought, eagerly watching for the effects of light and shade, composition and expression, as they gradually grew into shape upon the plate, just as he exultantly exclaimed that they were all right, he found that the developer, gathering into separate streams, as he held the plate up to the light, covered the negative with streaks which utterly spoiled the picture!

How often a portrait has lost its chief value, expression, by delay in having a plate ready! The sitter has been posed and arranged with care, skill, and tact. A pleasant flow of conversation has been maintained, and he is interested, and the face is full of life and natural expression. If now the plate were ready for exposure, and a few seconds would suffice for that exposure, what an admirable and satisfactory likeness might be secured! But it unfortunately happens that the wet plate would have been deteriorating if it had been in the dark slide waiting, and so its preparation has been delayed until the last moment, and a brief delay is necessary after the sitter is ready. That delay is fatal to expression: sometimes also to position, as the sitter shrinks from the spirited pose of a moment ago; sometimes even to stillness, as a nervous unsteadiness is engendered by the uneasy moments of waiting. In fine, the portrait is spoiled.

It is unnecessary to dwell upon a multitude of other similar troubles attendant upon the delays involved in the use of plates which must be prepared upon the spot, while the sitter is waiting. The advantages, on the other hand, of having a stock of sensitive plates always at hand, ready for immediate use without a moment's delay, are self-evident, as are also the aids to artistic success which such material facilities place in the hands of the artistic portraitist. It is to another series of facilities for which the use of dry plates in the studio presents especial openings we should now direct attention. The legitimacy of artistic aids to success in producing pictorial effects in photography is generally felt by portraitists. Judicious retouching is universally admitted, and wherever the

pencil can lend genuine improvements to the photograph, there can be little doubt of the propriety of the photographer availing himself of its use. The plan to which we refer is described by Mr. Eastham in our recently issued YEAR-BOOK. To some extent it has been employed before, especially in producing enlargements. We refer to the plan of producing a transparency from the original negative, and working on that transparency, a method which permits ameliorations considerably greater than can be produced by working on the negative. In a paper read before the South London Photographic Society some years ago Mr. Croughton pointed out these facts. In touching upon the negative, lights alone can be strengthened or added, the shadows cannot be modified. In working on the transparency, shadows, the most important part of the subject pictorially, can be modified, strengthened, or added. The light and shade of the background can be wonderfully modified, or fresh objects added. Mr. Eastham uses a matt varnish on the back of the plate, and with a stump and black lead, or crayons, almost any effect may be produced to which the draughtsman's skill is equal. Or adopting the ingenious suggestion of Mr. Werge, by using the powder process, a landscape or interior may be added by using a suitable negative. The variety of effects possible in this way will occur to every artistic photographer.

The transparency having been duly treated, the reproduction of a negative from it is a simple affair. The simplicity and ease with which negatives can be reproduced in this way by means of dry plates is the point worthy the attention of the portraitist. As Mr. Eastham points out, a few seconds' exposure to an ordinary gas burner, of the sensitive plate under the negative, produces the result. From the completed negative every print is a finished work of art, suggesting the idea that it has received many hours' work from an accomplished artist. We have seen such results as we describe. Need we say more? *Verbum sap. sat.*

THE PHOTOGRAPHIC UNION OF FRANCE.

THE following letter has been addressed by the recently established Photographic Union of France to Monsieur Levitzky, of St. Petersburg, photographer by appointment to the Court of Russia, and Vice-President of the International Jury of Class 12, Group 2, at the late Paris Exhibition.

DEAR SIR AND HONOURED COLLEAGUE.—A new Photographic Society has recently been established at Paris, under the name of the *Union Photographique de France*. At the first meeting of this association, when its statutes were adopted and its executive council elected, it was determined, on the proposition of MM. Carjat and Liébert, that a vote of thanks should be tendered to you for the course of action that you maintained on the Photographic Jury of the late International Exhibition at Paris.

It is well known, dear sir, and the photographic world congratulates itself on being able to acknowledge, that the interests of photography have found in you a zealous and devoted advocate. That the decisions of the jury were not always in accordance with those notions of justice which ought to guide every body of men charged officially with the awarding of recompenses of merit, was not in any way due to you. Though your able and honourable exertions were not always crowned with success, all those who take an interest in the future of photography are not the less eager to thank you for using them.

We are therefore, dear sir, delighted to be able to discharge ourselves of the agreeable duty which the Photographic Union of France has laid upon us. In transmitting to you the vote of thanks which was carried by acclamation, we have pleasure in assuring you that it is rendered not less to the Vice-President of the Jury, than to the individual who has left here among his colleagues so many sincere and heartfelt recollections.

Members of the Executive Council of the Photographic Union of France.

MR. LE NEVE FOSTER, M.A.

It is with deep regret that we announce the sudden death of Mr. Peter le Neve Foster, the well known and greatly respected Secretary of the Society of Arts. Since Christmas last Mr. Foster has been suffering rather severely from the gout, but it was hoped that the disease had left him, and he was recently enabled to resume his duties at the Society. On Thursday last, however, immediately on his return home to his own house at Wandsworth, he was seized with a sudden attack of heart disease, and some of his family coming into the room, where he had been sitting by himself for a few minutes reading the newspaper, found that he had fallen back from his chair dead.

So little expected was the illness that he had finished his ordinary day's work at his office, and had even walked up from the railway station to his own house.

Mr. Foster was born on the 17th August, 1809, and was the son of Mr. Peter Le Neve Foster, of Lenwade, Norfolk. He was educated under Dr. Valpy at the Norwich Grammar School, from whence he went up to Trinity Hall, Cambridge. After having taken his degree as thirty-eighth wrangler in the Mathematical Trips of 1830, he was elected Fellow of his College. He was called to the Bar at the Middle Temple in 1836, and practised as a Conveyancer till he became Secretary to the Society of Arts in 1853.

Mr. Foster was intimately associated with all the earlier great exhibitions. He was appointed to carry into effect the provisions of the Act for the protection of inventions in the Exhibition of 1851, and was also named treasurer for payment of all executive expenses in the original commission.

During his term of office, the Society of Arts has flourished as it never previously did, and, owing in no small degree to his exertions, it has quadrupled its number of members, and increased its resources in a still greater proportion. Much of its work was originated by the late secretary, and all of it was carried out by him. Even the regular working of such a society involves no small amount of labour and responsibility; but, besides this, the Society has been instrumental in promoting a great many public objects, and in all these it was necessarily upon the secretary that the burden of the work always fell.

From his boyhood upwards, Mr. Foster took a keen and enlightened interest in many branches of science. He was one of the first to take up and practise as a scientific amateur the art of photography, and on this subject he has written a good deal in the pages of the photographic and other periodicals. For many years past our YEAR-BOOK has been indebted to his pen for interesting contributions. He was one of the founders of the Photographic Society, and was on its council for many years. He was President of the Queckett Microscopical Club for a year, and also served for some time on the Council of the British Association, the meetings of which he has attended regularly for the past twenty years. For many years he acted as Secretary of the Mechanical Section of the Association. He read several papers before the Society of Arts, and was, of course, a constant contributor to its Journal, the whole series of which, from the middle of the first volume, was published under his direction.

Mr. Foster leaves behind him a very numerous body of friends, to all of whom his genial and kindly character had endeared him. There must be literally some thousands of persons who have profited by the ready advice and generous help which were at the service of all applicants, known or unknown, who came to the office in the Adelphi.

On the occasion of his completion of twenty-five years' service as Secretary, a strong committee was formed to present Mr. Foster with a testimonial. The list for this was just about to be closed, the amount subscribed being over £1,200. Under present circumstances it is probable that a fresh effort will be made to increase this amount, so that a fitting memorial may be presented to Mrs. Foster.

A GOOD MOUNTING MATERIAL.

BY FRANCIS DANN.

THE following has been found an excellent mounting material for both carbon and silver prints. It is very adhesive, does not *penetrate* the paper nor destroy the brilliancy of the prints, and is convenient to use.

Dissolve 16 ounces of good French glue in 30 ounces of water, to which add 80 grains of shellac dissolved in one ounce of methylated spirit, and stir them well together while hot.

Dissolve 6 ounces of dextrine in 8 ounces of methylated spirit and 4 ounces of water; stir well together in a glass beaker, and place it in a saucepan of hot water until dissolved, and of a clear brown colour, when it must be added and well stirred with the glue.

The above quantity may safely be made and poured into a dish or mould for use when required, pieces being cut therefrom as necessary. It is made ready for use by applying heat sufficient to liquefy it.

Royal Arsenal, Woolwich.

LIGHT, AND ITS WORK IN ABSORPTION.

BY CAPT. W. DE W. ABNEY, R.E., F.R.S.*

BEFORE this candle flame I hold a piece of glass, and you would say that the flame appears violet through it. Why is it violet? Let us consult the spectrum and obtain an answer. I place the glass before the slit of the lamp, and you see that the whole of our band of colour is absent except a band in the red, a faint band in the yellow, and a wide band of blue. Now a mixture of red and blue light gives us the sensation of violet, in the same way that a mixture of all the colours of the spectrum gives us the sensation of white light.

The question now arises, what has become of the yellow and other rays? All radiation, where it falls upon a body, must do one of three things: it must be reflected, transmitted, or absorbed. In the case of the blue glass, the yellow rays have been absorbed, whilst the blue and some of the red are transmitted, and there is a certain amount of surface reflection. When we say *absorbed*, we mean the waves have been quenched, and the energy they carry has been utilized in some way. What has become of the energy? Let us answer this question by another experiment. Here I have a piece of glass coated with common lampblack, and when I place it before the slit you will see that it cuts off nearly all the rays. I think now that I can show you what has become of the energy.

Here I have a glass bulb coated with lampblack and a stem with three bends in it, in which is located coloured liquid. I now cut off by a card all radiations except the visible ones, and the others I collect by a lens and expose the bulb to rays thus collected. The liquid is found down in the stem; in other words, the air inside has expanded, and expansion of the air shows heating.

If I take a mercurial thermometer, and do the same, the same result ensues, the mercury expands, the particles get into more violent motion than is their wont, and they become further separated in consequence. Now then we can tell what has become of the energy; the lampblack has absorbed the radiations, its particles become violently agitated, but only so as to cause radiations of large wave lengths, which are therefore invisible; they communicate their agitation to the particles of the glass, and the glass to the air or mercury. The energy carried by the radiations has been expended in the work of separating the particles of air in one case, and the particles of mercury in the other; the swinging particles in the lamp have communicated their motion to the particles of the air and of the mercury. In other words, we have a *transference from one body to another of the molecular motion which we call heat*.

Now for our violet glass. What becomes of the energy of our radiations in that case? It does not absorb all the radiations, but only part, and the energy conveyed by these arrested waves is transferred to it in the shape of heat, and if exposed long enough to the radiations, the rise in temperature might be sensible to the touch; the touch, remember, depending on the transference of vibration of the heated body to the nerves situated in our epidermis.

We will now place other coloured glasses before the screen, and note the absorption that takes place in them. 1st. We have a red glass, which you will see cuts off all the blue from the spectrum, and leaves the red intact and a slight band of green. If I place the violet glass in front of this again, we should expect that a red band alone should remain, since the red glass absorbs everything that blue allows to pass through except the red of the spectrum. You see this is the case. Here we have a green glass which transmits the green and yellow, but cuts off the blue and most of the red. You will notice that the small amount of red light left occupies a different position to the red which passed through the red or the blue glass. Hence, if we combine all the glasses together, no light should pass through them. Our conjecture, you see, is practically proved: the spectrum entirely disappears, and we have darkness. What has become of the energy of the colour-giving waves radiating from the glowing carbon points which have struck our glasses? They have been doing work in the interior of the glasses, shaking the particles and raising their temperature.

Let us test some coloured liquids, and see whether they likewise absorb. I place the purple potassium permanganate dissolved in water before the slit, and we have thorough proof that absorption is taking place. We see that in the yellow and green we have an immense elimination of colour, and four or five black bands appear in these regions. Again, I will rapidly pass potassium chromate, Spiller's purple, cyanine blue, and other dyes, before the slit, and in every case we have the colours left on the screen which, if combined, would give the colour of the liquid. As before, the absorbed waves do internal work in the liquids, causing a rise in temperature, though so small as to be imperceptible, unless extremely delicate means are taken of showing it.

We have now tested both solids and liquids for absorption, but I would next like to show you the absorption of gases and vapours.

Those gases which we meet with ordinarily in nature are colourless, and any power of absorption that they possess lies in the radiations outside the visible band of colour or spectrum. These radiations we shall not examine, for being invisible they do not come under the head of "light." There are other gases, however, which are more or less intensely coloured, which are to be found in combination in bodies. Such a gas I have here—nitrous acid. If I hold this up to white light, you will see that it is strongly coloured with a brown tint, and hence we may infer that it has the power of cutting off the blue rays. Let us try if this is the case by placing it in the spectrum.

See, the blue rays are cut off, which is what we might have expected. What becomes of the energy carried by these absorbed rays? It is expended, as before, as a heating effect, though unless very great precautions are taken, the small rise in temperature is not apparent. So I might go on and show you the absorption due to other gases, but I should prolong this part of my subject beyond reasonable limits. Now as to vapours, can I show you that these absorb? Were I to take the colourless vapours of such substances as ether and alcohol, I could not show you that they have any appreciable absorption of the visible spectrum, since they, too, are colourless; but I can show you the absorption by metalloidal vapours.

In this large flask I have dropped one or two drops of the liquid metalloidal bromine, and its vapour now fills the flask. It has an orange tint when viewed by white light,

and it ought to behave in a somewhat similar manner to the nitrous acid which we have just now experimented with. Placing it before the slit, we see that it does do so, but the phenomenon is varied if a close scrutiny be made, for the absorption is found to be due to cutting off small lines of light in the blue and the yellow, these lines being equidistant from one another. The general effect, however, is the same as with the nitrous oxide.

In this test-tube I have some iodine, which I will gently warm. The iodine vapour fills the tube, and we see that it is of a purple colour, hardly to be distinguished, in fact, from that of the permanganate of potash solution. I hold it in front of the slit. At first, whilst the vapour is very dense, we have a total, or nearly total, absorption of the yellow and green; but I would have you notice that as the vapour gets less dense, owing to its cooling and depositing in the top of the tube, the band of absorption narrows, first at the top and then at the bottom, until, finally, both the yellow and green are to be seen on the screen. Like bromine, these absorption bands are formed by an innumerable number of fine lines very closely situated together.

It is an interesting experiment to hold these tubes and flasks containing the various gases, vapours, and solutions at a small distance from the screen in the spectrum, and to note the intensity of the shadows they cast when they traverse the part of the spectrum which their contents absorb. Thus we find that the flask of bromine casts no shadow in the red, whereas in the blue the shadow is jet black.

Once more. Let us see the absorption that takes place by a metallic vapour. You are aware that common salt is composed of metallic sodium combined with chlorine. I will take a little of this sodium, and, after separating the carbon points, will place it on the lower one, and we shall see that when vaporized by bringing the carbon points together it likewise exercises an absorption. I can burn this metal because it has a great affinity for oxygen, and the rapidity of combination is such that the temperature of the metallic sodium is raised, and we get the sodium given off as a vapour; not colourless like the metal which I hold here, but of a bright yellow tint. I bring the points together, and the sodium immediately gets volatilized, the glowing points of carbon are surrounded by the yellow sodium vapour, and on the screen we have a wonderful case of absorption. How is this? The flame is yellow, and yet we find that the yellow of the spectrum is cut off. Is not this an apparent contradiction of what has gone before—that a yellow vapour absorbs the yellow. It is not, for this reason: in this case we are dealing with a vapour which itself is self-luminous, and the rays absorbed by a cold body are always radiated by it when hot. Let us test this. Here I have a salt of cobalt in solution, which is blue by transmitted light, and therefore cuts off the red. I take a pen and write, with the solution as ink, upon a piece of clean platinum foil, and hold it in this colourless flame. You will note that the marks I have made shine out with a red light on the white hot platinum background; in other words, the cobalt salt, when hot, emits the same light as it absorbs when cold. So with our sodium, its hot vapour absorbs the same rays that it emits, and cold sodium vapour, if it could exist, would still cut off the yellow rays; in fact, it would appear purplish by transmitted light.

(To be continued.)

COLONEL WORTLEY'S INSTANTANEOUS SHUTTER.

The principle of the instantaneous shutter, which was exhibited at the last meeting of the Society, will be understood by a reference to the accompanying figure.

At the back of the narrow box in which the movable parts are situated is a projecting grooved piece (not shown) which replaces the ordinary camera front. In the opening

of the box is fitted a board which carries the lens in the ordinary manner, and is fastened by B B. The lens occupies a position facing M, which is a circular aperture in the back of the box, and opening into the camera. *aaaa* is a rectangular sheet of brass, in which a circular hole, C, has been drilled (of about the same diameter as M), and provided with two movable wings, W W, by which it

can be more or less closed, the sky in almost every case having less exposure given to it when the apparatus is used. In *aaaa* are two notches into which the ratchet, K, falls, K being raised when required by pressing down the thick pin shown on the top. One of the notches is seen at G, the other is so arranged that when K falls into it C is exactly opposite M, in which position of the brass plate the usual focussing operations can be performed. An india-rubber band, S S (fixed as shown), pulls *aaaa* across the aperture M, when K is released. The string D pulls back the sliding brass plate till K falls into one or other of the notches.—*Photographic Journal*.

Recent Patents.

PORTRAITS BY ARTIFICIAL LIGHT.

BY G. E. ALDER AND J. A. CLARKE.

THE following is the specification of the arrangement for using artificial light for portraiture, known as the Luxograph:—

Our invention has for its object the production of photographs without the aid of daylight, and at times and in places where it would ordinarily be impossible to produce them.

We use any of the well-known actinic artificial lights, such as the electric, magnesium, or pyrotechnic compounds, by preference the pyrotechnic, on account of its not requiring expensive apparatus and machinery. It is well known, however, that unaided artificial light is useless for the production of satisfactory pictures, as rays of light coming from a point are quite unsuitable for the purpose. Our invention enables the operator to produce pictures equal to those taken by ordinary daylight. For this purpose we employ a reflector of suitable size, by preference one about four or five feet in diameter, in conjunction with the said light, and with the reflecting surfaces placed at suitable angles; we prefer to render the rays of light parallel or convergent to a focus. In conjunction with the reflector or otherwise we employ one or more semi-transparent screens placed between the source of light and the object to be photographed, by which means the rays of light are dispersed or diffused equally, and a soft and suitable light obtained for photographic purposes.

Improvements are to be performed by making the reflectors of silvered glass or other reflecting surfaces built up of small pieces, or otherwise formed, and fixed in a curved or other convenient shaped metal or otherwise constructed frame. In front of the reflector and in its centre of focus is placed the light, and in front of the light is placed one or more screens of opal or ground glass, or of papier mineral, tinted or otherwise, or other semi-transparent media of sufficient size to prevent the passage of any rays of light, save through its medium, and thus all rays are dispersed.

In practice we often find it desirable to subdue the principal light by placing a violet or blue tinted glass in front of it.

When either a pyrotechnic composition or magnesium is employed to produce the light a lantern of glass must be used with a chimney to carry off the fumes arising from the burning of the light, and the light supplied with air by suitable inlet.

Having thus declared the nature of our said invention, and the manner in which it is performed, we claim,—

Firstly. One or more screens in conjunction with artificial light for diffusing the rays of said light.

Secondly. One or more suitable reflectors for multiplying rays of artificial light and reflecting them at proper angles, in combination with one or more semi-transparent media for diffusing said rays, all for the purpose of illuminating objects for photographic purposes, all substantially as described and set forth.

Correspondence.

DEATH OF MRS. CAMERON.

DEAR SIR,—Many of your readers will be grieved to hear the announcement of the death of Mrs. Julia Margaret Cameron, who died at Gleucairn, Dikoya, Ceylon, on Sunday last, after a short illness from a cold caught while nursing one of her sons, who had been ill for some time.

Mrs. Cameron's productions when in England are too well known and appreciated to require any comment, and since her residence in Ceylon her camera has been seldom idle; in fact, a more indefatigable lady never existed.

In addition to her artistic skill and taste, Mrs. Cameron was a poetess of no mean order, and her varied accomplishments made her the centre of a highly intellectual circle. Her many excellent qualities endeared her to the hearts of all who knew her, and all who had the honour of her acquaintance recognized her womanly worth, and have offered their tribute of affectionate regard for her memory.

Well do I remember, on first meeting Mrs. Cameron a few days after landing in Ceylon, being struck with the kind, motherly manner in which she gave me a host of useful advice about preserving my health in this tropical climate, irresistibly attracting love and respect.—I remain, yours respectfully,

W. T. WILKINSON.

Colombo, Ceylon, Jan. 30th.

KEEPING PYROXYLINE.

DEAR SIR,—With reference to some remarks which lately appeared in the NEWS on the subject of keeping pyroxyline, I beg to record my experience in that direction.

When in India some years ago, I on two or three occasions obtained pyroxyline from a well-known London firm. They sent it me in stoppered bottles, and it invariably reached me in a state of decomposition,—usually as a pasty mass, with the bottle full of nitrous fumes. I informed the firm which supplied me, thinking that the pyroxyline was perhaps insufficiently washed. Every batch I received, however, arrived in a similar state; so I determined to obtain the acids and make the pyroxyline myself. This I did, and never found that it decomposed in any way. It was kept loosely-wrapped in paper, and placed in a tin box with holes in it. Since then I made several ounces of pyroxyline in England to take out to India, as I had found it difficult to obtain acids of suitable strength in the country. This cotton was taken out to India packed in the manner described; and as I seldom had leisure for photography, the pyroxyline was not used up for three or four years. No decomposition of any kind set in, and during the hot season the thermometer in the house must often have stood at 100°.

I may mention that the pyroxyline I have referred to as having been obtained from London, and also the samples I made in India, were made by Hardwich's formula; that which I made in quantity in England, and kept for three or four years in India, was made by the formula given in the YEAR-BOOK.—Yours faithfully, W. L. NOVERRE, Major.

PYROTECHNIC COMPOUND.

STR,—The composition formerly in use in the theatres for lighting up ghosts, &c., was as under:—

Nitre	5 ounces
Sulphur	2 "
Antimony	1 ounce

each article pounded in a mortar, well dried, and then mixed. A couple of ounces formed into a cone on a piece of tin or iron, and lit with a match, would give a very intense light. Probably the modern blue fire makers may have improved upon this—or what was formerly known as "Gaudin's Fire," made of

Chlorate potass	6 ounces
Sulphur	1½ "
Sugar	½ "

Yours, &c., THE OLD HAND.

Notes and Queries.

STR,—Would you kindly answer the following query in your next, and greatly oblige.

"During a sudden thaw in January last, my cellar, in which stood a keg containing about half a cwt. of hypo, was flooded to the depth of some nine inches, the consequence being that the floor was saturated with hypo in solution. The floor is of sound asphalt, but my operating rooms, &c., being just above, I much fear the consequences of the hypo particles being carried upstairs on the soles of boots, or otherwise. Is there any chemical I could wash the floor with effectually, or which I could lay down to combine with the hypo, so that I could remove it in composition; or what course would you recommend?—Yours respectfully, "Q. H."

[Can any of our readers suggest a remedy for this disaster?—Ed.]

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

"Annual Report, 1879.

"YOUR Council, in reviewing the work of the last year, have every reason to be gratified at the progress that has been made in photography in general. When the list of papers given below is scanned, it will be noticed what varied subjects have been brought before the Society at its meetings, and the information brought out on these occasions has evidently had a most beneficial effect upon the attendance at the meetings. The progress in the science of photography since the last annual meeting has been noticeable, for it will be found that much which has been unexplained before in certain photographic phenomena have been tracked to their origin, and evidence has been adduced that the term "actinic" must be applied to the whole range of the spectrum. A step in the proof that light, radiant heat, and chemical action are simply effects of radiation, and not forces inherent in it, has thus been made, a step which is important in physical science generally. As regards dry-plate processes, more particularly emulsion processes, the Society have had the benefit of the experience and teachings of several members who are entitled to speak with authority, and this is the more noticeable in that the prize which has been offered by Mr. Paget might have been supposed to have temporarily closed the sources of information in such matters. In the matter of permanent printing, the knowledge of the possibility of the fading of carbon prints has been amply discussed, and the conclusion arrived at must, to a very large extent, have satisfied those interested in their production as to their permanence.

"In the improved platinotype process, which was brought before the British Association at Dublin, and subsequently before the Society by the inventor, is to be found another process which, from chemical considerations, must prove valuable for producing pictures which can also be relied upon for permanence. The abolition of hyposulphite of soda and silver from the process, and the sole employment of such indetructible matter as platinum black, as the colourant of the images, is a great advance on the original process. The introduction of this amended form of the

platinotype process may be said to be one great feature in the year's advance.

"Your Council have great pleasure in formally recording in their report that the Progress Medal for the greatest advances in the science or art of photography was awarded for the first time during the past year, and that the award was made to Captain Abney, R.E., F.R.S., for his recent researches in photographic science. The Progress Medal differs in many respects from the medals offered at the annual exhibitions, in that some distinct advance must be made before it can be awarded, and in order to make it a prize which should excite the emulation of all workers, your Council consider that it should be withheld until some noticeable advance had been made. The award is still under the consideration of the council.

"During the ensuing year the first triennial examination in photography will be held under the auspices of the Society of Arts, and it is hoped that the small prizes offered to the successful competitors by this Society will aid in furthering the objects which it had in view when it applied to the Society of Arts to hold such examinations. The technical examination will include a theoretical knowledge of the subject which must strongly stimulate honest work in the art-science, and the passing of the examination ought to stamp the examined as having studied his subject in other than a rule-of-thumb manner. Your Council have caused the requirements of the Society of Arts to be inserted in the Journal.

"Your Council have already referred to the prize offered by Mr. Paget in connection with dry plate work, the award of which they have undertaken through a competent committee of the Society. They would desire to express their sense of the munificence of the offer made by Mr. Paget, marking, as it does, the interest which one of their members takes in the advancement of photography. Should the outcome of the competition be to give to the public a process which fulfils the conditions insisted upon, the boon will be no slight one.

"In connection with the Exhibition (which was satisfactory, when the fact is considered that many valued members threw their strength into the Paris Exhibition) your Council have to notice the introduction of an entirely new feature, viz.: the charging for wall space to non-members. The policy of this innovation is evident, when it is taken into consideration that an annual exhibition exists as much for the benefit of the exhibitors as for the art itself. It is, therefore, manifestly right that those who are not members, and yet partake of one of its advantages, should support the Exhibition in some other way. The experiment having been tried, the result has been most satisfactory, and your Society has obtained many additional numbers by a strict adherence to the rules laid down.

"The following analysis of the Exhibition is again recorded, as statistics constitute the base upon which are founded new possibilities in policy and government:—There were 94 exhibitors, comprising 43 members, and 51 non-members. Of the 43 members, 27 were resident in London; 16 in the country. Of the 51 non-members, 20 from London, and 31 from the country. There were 47 London exhibitors, and 47 country exhibitors. 331 frames were hung, containing 897 separate photographs. Of these, 401 were portraits and figure subjects, 422 landscapes and architecture, 33 animals, and 41 miscellaneous. The Russian loan collection and the Cyprus pictures amounted to 851, making a total of 1,743 pictorial works exhibited.

"Your Council with sorrow have to record the death of two distinguished members of the Society, viz., J. A. Spencer, and T. Sopwith, F.R.S., obituary notices of whom will be found at the conclusion of the report.

"The following papers have been read during the past year, and show that a wide range of subjects have been brought for discussion:—'On the Fading of Carbon Prints, and the Suppression of Bichromates in Carbon Printing,' by Dr. D. Van Monekhoven; 'Non-converging Perpendiculars in Architectural Photography,' by Edwin Cocking; 'Remarks on Dr. Monekhoven's Paper,' by W. S. Bird; 'Remarks on Dr. Monekhoven's Paper,' by J. W. Swan; 'Photography at the Least R-frangible End of the Spectrum, and on some Photographic Phenomena,' by Captain Abney, R.E., F.R.S.; 'On Dry Plate Process,' by W. England; 'A Tourist's Preservative Dry Plate Process,' by T. Sebastian Davies, F.C.S.; 'On Alizarine: its Origin, Properties, and Applications,' by J. R. Johnson; 'On the Alleged Fading of Carbon Prints,' by Thomas Bolas, F.C.S.; 'Photographic Notes from a Travel in Russia, with Exhibition of Various Works, Apparatus, and Material,' by Leon Warnerke; 'Photographic Experience in Cyprus,' by John

Thompson, F.R.G.S.; 'A Really Reliable Dry Plate Process,' by Henry Cooper; 'A Case of the Destruction of the Latent Image on Washed Collodion, and its Restoration,' by Leon Warnerke; 'Notes on the Platinotype Process,' by W. Willis, jun.; 'On the Subjective and Objective of Pictorial Photography,' by Edw. Coeking; 'On the Fading of the Undeveloped Photographie Image, and on Soluble Bromide in Emulsions,' by Captain Abney, R.E., F.R.S.; 'On an Instantaneous Shutter,' by Colonel H. Stuart Wortley.

"In conclusion, your Council congratulate your Society upon the work done during the past year, and trust that as the future of our art-science unfolds fresh matter for investigation, all members will avail themselves of the ordinary meetings to discuss new theories or facts in photography.

"Obituary.

"JOHN A. SPENCER, born in Lamb's Conduit Street, in 1827, where his father followed the business of a chemist. Educated at University College, he devoted himself to chemical science, studying under Dr. Hofmann. At length succeeded to his father's business, and for the excellence of his chemical preparations was awarded one of the few bronze medals given for that class of manufactures at the Great Exhibition in 1851. Soon after this time he was appointed Demonstrator of Applied Chemistry at the Panopticon, now the Alhambra, in Leicester Square. He seems to have turned his attention to photography about the year 1853, and in 1856 produced for the Arundel Society the illustrations to the late Sir Digby Wyatt's 'Notices of Sculpture in Ivory.' Soon after this Mr. Spencer went into business extensively as a manufacturer of albumenized paper. The care with which this paper was prepared and its freedom from defects soon obtained for it a very large sale, and 'Spencer's Albumenized Paper' acquired a very good position in the market. About 1867 Mr. Spencer commenced the manufacture of carbon tissue, and in the year 1870 joined the Autotype Company. Mr. Spencer retired from the business in January 1877, and but a few months after the promontory symptoms of a very painful disease appeared, which carried him off on the 20th of April, 1878, aged 51. He was interred in the Hammersmith Cemetery. Mr. Spencer was a most excellent chemist, singularly urbane and genial in manner. He was an early member of the Volunteer Corps, and of late years held the rank of Captain in the South Middlesex Regiment. His death at a comparatively early age weakened the ranks of the photographic profession by removing one who possessed a large amount of technical and manipulatory skill, combined with an amount of chemical knowledge consequent upon a very efficient training in early life.

"Mr. THOMAS SOPWITH, M.A., F.R.S., was born at Newcastle in the year 1803. In early life he gave evidence for taste of design and construction, and at first studied architecture. From architecture he passed to the study of mining and railway engineering. In the year 1838 he was appointed Commissioner for the Crown under the Dean Forest Mining Act. At this time he had published a treatise on 'Isometrical Drawing, as applicable to Geological and Mining Plans, Picturesque Delineation, Ornamental Grounds, &c., &c.' Other works published by him were: 'Geological Sections of Holyhead,' 'Hudgill Cross Vein and Silver Band Lead Mines in Alston Moor and Teesdale,' showing the various strata and subterranean operations. He was the inventor of a set of projecting and parallel rulers, for constructing and working plans and drawings in isometrical and other models by projection, and of a most useful levelling staff. Mr. Sopwith, by his representations, &c., was chiefly instrumental in the formation of the Mining Records Office. From 1845 to the year 1871 he was mining engineer at the extensive Lead Mines at Allenheads. He here studied botany, geology, meteorology, and mineralogy. From 1871 he resided chiefly in London, and attended regularly most of the meetings of scientific societies. He was genial, and had great conversational powers. He was a great lover of art, and ever took great interest in photography, both in respect to its scientific and artistic associations. He was colleague of our President as joint referee at the Amateur Photographic Association, and his careful criticism at times of determining the pictures for prizes was most valuable. His diary, extending over 168 beautifully written volumes, contains the principal incidents in his very active and useful life."

MANCHESTER PHOTOGRAPHIC SOCIETY.

The annual extra meeting of this Society took place in the large room of the Memorial Hall, Albert Square, February 13th, the President (Mr. CHARLES ADIN) in the chair.

The minutes of the previous meeting were read and confirmed, after which

Mr. AMBLES read a paper, "Reminiscences of a Photographic Visit to Germany" (in our next).

Mr. W. J. CHADWICK then read a short communication on "Patents in Connection with Photography by Artificial Light" (see page 98). He also exhibited some portraits taken by artificial light, four of which were done in 1869, by the light of Moule's photogen. One of these apparatus had been sent down for trial at the meeting, but, owing to its late arrival, the experiments were postponed.

A somewhat interesting discussion followed, upon the nature and merits of the different artificial lights, which proved so highly interesting that it was desired another evening should be devoted to the subject, the Secretary being commissioned to arrange an artificial light evening in connection with photography at an early opportunity.

Mr. POLLITT (in fulfilment of his promise at the last meeting) had brought a fine view of the interior of a large drapery establishment in Manchester, which he had taken by aid of the electric light.

A large quantity of landscapes were shown by Mr. Coote, Leigh, Garside, and others, and some very fine portraits by Mr. Gregory; also, a magnificent autotype enlargement was exhibited by Messrs. Hellewell and Sons.

The SECRETARY said, in order to make the meeting as interesting as possible, he thought something more than a good knife-and-fork tea, to which they had already done justice, would be appreciated. He had, therefore, collected a quantity of pictures and apparatus from various sources.

Mr. WM. BROOKS, of Reigate, had sent two series of subterranean photography (the caves of Reigate); these photographs were taken on gelatine plates by the light of ordinary paraffin lamps. Mr. Brooks also sent several fine enlargements printed from collodio-bromide negatives, which were examined by the members with great interest and admiration.

A novelty in cameras was exhibited by Messrs. W. W. Ronch and Co.

Two very portable cameras, with tripods and lenses complete, by Messrs. J. Fleury Hermagis, of Paris; Messrs. Marion had sent down one of their excellent rolling presses, a pair of Hemery's self-registering printing-frames, and a Cadett's pneumatic shutter; and Messrs. Avery and Co. had forwarded a background of their new material.

Mr. W. J. CHADWICK exhibited a lecturer's complete lantern outfit (with the exception of the oxygen apparatus that had already been before the members on one or two occasions). The lantern was a bi-unial, and though of small size, perfect ventilation was secured. This instrument was mounted upon its packing-box, which was designed with doors to form a table on each side of the lantern, and was supported on one of Messrs. Oakley's adjustable tripods; the screen was supported on a very neat and convenient portable frame supplied by Mr. J. H. Steward; and a portable reading desk and lamp by Mr. Middleton.

After all the photographs and apparatus had been well viewed and examined by the members and their friends (who mustered near upon seventy),

A good collection of transparencies were shown on the large screen by the magic lantern, the manipulation of which was very ably conducted by Mr. G. A. Brooks. After the members' slides had been shown, some very beautiful ones were exhibited which Mr. W. Brooks, of Reigate, had also sent down; these were printed upon collodio-bromide emulsion plates, and their colour, clearness, and general beauty were much appreciated.

A fine collection of Woodbury slides were next shown, concluding with a splendid series representing clouds, water, and shipping, by Mr. Valentine, of Dundee.

A vote of thanks was passed to all who had contributed to so highly an interesting meeting, and at a late hour the proceedings terminated.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting was held at the usual place, The Museum, Queen's Road, Bristol, on Wednesday, February 5th, Mr. RADCLIFFE in the chair.

The minutes having been confirmed,

The CHAIRMAN exhibited a very complete and well-designed little actinometer, which elicited much interest and favourable comment on its help in carbon printing.

Mr. BIGGS spoke of a peculiar appearance on the surface of carbon paper after printing, and which, after practice, he found was a guide to a certain extent.

Mr. RADCLIFFE endorsed the former speaker's remarks, stating that he had noticed the same appearance.

Mr. BIGGS spoke of his mode of keeping sensitized paper, which was by laying it between sheets of soda blotting-paper; on looking at ready sensitized paper, it seemed as if there were a thin or slight varnish over the surface, which dissolved during use.

Mr. E. BRIGHTMAN then read a paper "On the Causes of Insolubility in Carbon Tissue," which was of a very interesting nature (page 98).

Mr. BIGGS remarked that he feared very few people gave the carbon tissue credit for being as sensitive as it was. He had seen some men preparing it in the twilight, and, after it had been hung to dry, taking it through the light in the least apprehensive manner. He had by experiment proved that carbon tissue was more sensitive to light than sensitized paper. He also considered the keeping properties of it very moderate.

Mr. BRIGHTMAN'S experience was that old carbon tissue gave a much more forcible picture than new; it seemed to ripen, as it were.

The CHAIRMAN stated that a man had experimented, and felt sure that such was the case, and, as a consequence, was going to manufacture tissue, and keep it so that it might age, so that anyone would then be able to buy it already matured.

The HON. SECRETARY exhibited a very fine carbon print of Sir Noel Paton's picture, "I wonder who lived in there!" representing a wondering little boy looking into an old helmet. It was the Edinburgh Society's presentation picture, and a copy of which they kindly sent for the Bristol and West of England Association's acceptance.

A vote of thanks, proposed by Mr. Brightman and seconded by Mr. Stevens, was accorded to the Edinburgh Society for kindly sending it.

A vote of thanks to Mr. Brightman for his paper closed the meeting.

Talk in the Studio.

THE PAGET PRIZE.—The dry plates (*in sealed packages*) and the negatives which are to be sent in for this competition on or before March 31st, should be addressed to T. S. Davis, Esq., Secretary to the Award Committee, 5A, Pall Mall East.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will take place at the rooms of the Society of Arts, Adelphi, on Thursday next, March 6th, at eight o'clock, when Mr. R. V. Harman will read a paper on "Artificial Lighting." Mr. F. A. Bridge will say a few words on "Finance," and Messrs. Ayres, Anckorn, and Mr. F. Henry will exhibit some apparatus, &c.

DEATH OF MRS. CAMERON.—We deeply regret to announce the death of Mrs. Cameron, a lady so well-known, and so justly esteemed in Ceylon, and indeed wherever she was known, that the announcement will send a pang of regret into many a household. The deceased lady had accompanied her son, Mr. Harding Cameron, who was ailing, from Kalutara to Glencairn in Dikoya, and was at that time apparently in perfect health, but it is feared a cold paved the way to the attack which proved fatal after a few days' illness, on Sunday last.—*Ceylon Times*, January 30th.

HARD TIMES.—A correspondent writes to us as follows:—"SIR,—Is photography going down? A few years back I was a tyro in the trade, and received a pound a week for doing nothing. Now, I have the ability to do something better, I can not find anything to do.

I have wander'd "Mighty London's" town,
Tramping after work to do;
Have wander'd up and wander'd down,
Tramping after work to do;
Have wander'd "Mighty London" round,
Tramping after work to do;
No "corn," save on my feet, I found,
Tramping after work to do.

A LITTLE PHOTO.

SODIUM HYPOSULPHITE AS A SENSITIVE COMPOUND.—A correspondent, writing to the *Society's Journal*, in one of his letters on the subject of sensitive compounds, says:—"I believe there is a great deal of rubbish talked about fixing and keeping your fixing solutions in the dark, and I do not do so myself. I cannot see what it can matter whether a soluble salt is dissolved away by hyposulphite in the light or in the dark."

In replying to this letter, there was occasion to allude to a fact which is not generally known, viz., that a solution of sodium hyposulphite is sensitive to light. In using this compound in volumetric analysis, it is always necessary to keep it in the dark, since in the light it decomposes with a precipitation of sulphur. By proper means a print may be obtained on paper by this decomposition; of course, more as a curiosity than as being of any real value.

THE MANUFACTURE OF HENS' EGGS.—One of the San Francisco papers gives an account of a new industry that has arisen in that city, namely, the manufacture of hens' eggs from inexpensive materials. The albumen is imitated by a mixture of sulphur, carbon, and fatty matter obtained from the slaughter-houses, and rendered sticky with mucilage. The yolk is made of blood, phosphate of lime, magnesia, muriate of ammonia, oleic and margaric acids, and coloured with chrome-yellow. The shells are shaped by a blow-pipe from a mass of gypsum (plaster of Paris), carbonate of lime, and oxide of iron. After the shells are blown, the albumen is forced in through a hole in the small end, and sticks to the sides; then the yolk is added, and after being covered with more of the albumen mixture the hole is sealed with cement; the complete egg is then "rubbed pretty smooth and laid aside for packing." It is asserted that many barrels of these eggs have been already shipped eastward for consumption; and as a pleasing adjunct to meat from the "slink butcher" they will no doubt be carefully welcomed by British shop-keepers in search of "cheap and nutritious" food.

To Correspondents.

ASTREA.—We do not know anything certain as to the composition of the substance in question. It is probable that your guess is tolerably correct. 2. We have given full instructions for nickel-plating in the *PHOTOGRAPHIC NEWS*. We are at present from home in pursuit of health, and have not facility to books of reference, nor can we give the date when details appeared in the *NEWS*. It is a few years ago. The solution would not hurt india-rubber; we cannot speak for paint. 3. Probably permanent photographic printing.

M. N.—The stain is beyond a question caused by hypo.

J. W.—We believe the salt is not in commerce. How the patentee prepares it we do not know; and as it is a patented process it is possible that he is not anxious to place facilities for piracy in the way of the public.

A FLOUNDERER.—We hope to give the article very shortly.

ANOTHER L.—We note the extract from the *Daily Telegraph*. So far as we know, the statement is an error; certainly it is as regards the occasion in question being the first introduction of the Luxograph. The writer, probably, thought this was the first occasion, and he thought his personal experience was the measure of the fact.

E. J. SCOTT.—We do not know any precise formula for the use of chlorides to secure warm tones in transparencies, but are familiar with the fact that chlorides are in some cases used for such purposes. The formulae have generally been kept secret. If we wished to produce such results, we should experiment upon the hint. There would be no need to dissolve the chloride in a small quantity of distilled water, as there are several chlorides soluble in alcohol. Try two grains of chloride of strontium to each ounce of bromo-iodized collodion. It will not do any harm to the bath. It may make the collodion a little slower. We can only suggest trying, unless some of our readers who are familiar with such a formula will communicate.

J. T. M.—So far as our experience and opportunity of observation go, developed prints are more permanent than albumenized prints; but they are much less pleasing. Being in the paper instead of on it, most probably contributes to permanency, but it detracts from beauty, giving a dull heavy look to the picture. The blacks are not perfectly black, and the whites rarely purely white.

PYRO.—We have within the last few months repeatedly given a formula such as you require. You should take the trouble to make a note of such formula when it appears, or to refer back to the numbers of the *NEWS*.

SOUTH DEVON.—We cannot at this moment make a precise reference. So far as our memory serves, an ounce in an ounce of water will make a saturated solution.

R. F. G.—The reason why india-rubber is not a satisfactory mounting material is its instability. It gradually decomposes, and, from being an elastic adhesive substance, it changes into a dry powdery resin. Pictures mounted with it leave the mount, and generally present a discoloured effect. The time it lasts depends on circumstances—perhaps six or eight years.

Several Correspondents in our next.

The Photographic News, March 7, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

HOW TO KEEP PYROXYLINE.—MRS. JULIA MARGARET CAMERON—ARCTIC PHOTOGRAPHS IN THE STUDIO.

How to Keep Pyroxyline.—Major Noverre's experience of photographer's guncotton, communicated in last week's NEWS, is interesting. He tells us that sample after sample sent out to him from England was in a fuming state when he received it in India. We can well believe it, for there are very few samples which, when kept in this country in closed vessels, do not show signs of decomposition after a while. We are speaking, *bien entendu*, of soluble pyroxyline only, and not of the more stable kind known as military guncotton. We fear, indeed, that it is very rarely the case that soluble guncotton is made which will bear sealing up at a temperature of 100° F. without showing signs of red fumes. The war chemist appears to be aware of the fact that soluble guncotton will not keep well, for if he find as much as twelve or fifteen per cent. in his military material, he rejects it as unfit for warlike purposes. Of course, if guncotton for torpedoes and mines could not be stored in magazines, it would be of little value to soldiers or sailors, from the fact that it would never be at hand at the moment it was wanted. Major Noverre says that to prevent the formation of fumes—or, rather, to allow these to escape, and not to exercise injury by their presence—he made it a practice to wrap up his guncotton very loosely in paper, and, moreover, provided the utensil in which it was stored with holes to allow access of air. This, or the immersion of the material in water, which at once preserves it, and, at the same time, renders it inert, is the only means of assuring oneself of the safe keeping of soluble guncotton. One need not, however, wait to see fumes given off to ascertain if incipient decomposition has begun. Long before the fumes are visible to the eye there arises an acid vapour, and this may at once be detected by the application of blue litmus paper. In conclusion, we may say that only the best and most stable guncotton, such as is employed in torpedoes and mines, is permitted in Government magazines, and it must pass a very crucial heat test. This is to place it in a closed vessel, and maintain it at a temperature of 150° F. for no less than a quarter of an hour. Under these severe conditions it must show no sign of acidity upon litmus paper, otherwise it is rejected. It would be impossible, of course, to make use of the same test in proving samples of soluble cotton, since, we believe, hardly a sample that is manufactured would be capable of passing, so that our readers will do well to follow the advice given by Major Noverre or by ourselves, if they desire to preserve their pyroxyline in good condition.

Mrs. Julia Margaret Cameron.—The death of Mrs. Julia Margaret Cameron at Ceylon leaves a blank in the list of artist photographers. Mrs. Cameron's productions were well known, and some of them—to wit, the portraits of Sir John Herschel and the Poet Laureate—were fine examples of camera work. To say that Mrs. Cameron's work was always satisfactory would be more than could be said of any artist; but that it was frequently most praiseworthy, and exerted a beneficial influence upon the disciples of the camera, few will deny. While Mrs. Cameron's detractors complained that the technical part of her work was slovenly done, and that "out-of-focus" constituted her principal motive, there were artists of standing and repute who praised her pictures without stint. If Mrs. Cameron's pictures were not perfect, they exercised an influence that was much wanted. Photographs small and sharp have been so much in vogue, that any efforts to impart more breadth in camera pictures were welcome.

Mr. Robert Crawshaw's prizes did much in the same way to throw the conventional photographer from his track; and although pictures taken direct, larger than life, were not always to be commended, there cannot be a doubt as to the influence of these larger portraits. Mrs. Cameron was an ardent believer in lack of sharpness, and if not universally in the right, she proved very plainly that pleasing pictures were to be produced of an un-sharp character, if we may use the expression, and that sharpness of focus was not, as photographers believed, the acme of photographic work. The fine portrait of Sir John Herschel, whose bold and rugged features were rendered so well by Mrs. Cameron, would have puzzled many a portraitist who went in for microscopic sharpness. In this case the lady did not err, as in some of her portraits she undoubtedly did, in producing blur, which, if carried too far, was obviously quite as much a defect as a painful sharpness in the skin of the model. Mrs. Cameron, too, was honest and straightforward in her art, and spared no pains to produce artistic results. She worked at her models again and again, and created a school of her own. As in the case of Rejlander, her art capacity was far greater than her technical skill; and if either of these had invoked the aid of one well skilled in photographic manipulation, the success of their pictures would have been much greater. In the case of one, as the other, many a fine production suffered from an accidental defect, which was all the more to be deplored because it might have been avoided. An occasional stain from development or the dipping bath, or want of attention in manipulation, whereby the picture was not "cleared up" as it should have been, has caused many a grumble on the part of critics; but these notwithstanding, Mrs. Cameron's photographs made their mark, and are not likely to be forgotten. The lesson they taught is certainly one by which most of us have profited. Mr. W. T. Wilkinson, who was the first to announce to us Mrs. Cameron's death, reminds us that the lady was something more than a worker with the camera. She had made Ceylon her residence for some time past, and since her arrival on the island her camera had never been idle. On Mr. Wilkinson's arrival on the island, she, in a "kind, motherly" fashion, gave him much advice as to the care of his health in the new climate, and generally interested herself in his welfare. No wonder, then, that he says: "In addition to her artistic skill and taste, Mrs. Cameron was a poetess of no mean order, and her varied accomplishments made her the centre of a highly intellectual circle. Her many excellent qualities endeared her to the hearts of all who knew her, and all who had the honour of her acquaintance recognized her womanly worth, and have offered their tribute of affectionate regard for her memory."

Arctic Photographs in the Studio.—Portraits with arctic surroundings are still prevalent on the Continent, and in America, although the charming pictures of Notman, of Montreal, of this nature, have not yet been surpassed. Snow and ice, but especially the former, are difficult things to simulate in the studio: a sheet of rough green glass, if properly set, will appear like a good imitation of ice, and salt may be made to appear like snow. But in America, where these pictures are the most successful, they employ, as a rule, very fine and soft down, which takes the impress of the foot, and has to all appearance the effect of pure driven snow. The soft pictures of Mr. Notman, indicative of a Canadian winter, are, we believe, all produced by the aid of white down of this description, which yields a lighter and softer image than a background of salt. The down, when permitted to settle on a roof, does so with all the characteristics of snow, and produces a charming cornice, such as one sees after a snow storm, when the flakes fall quickly and without drifting.

REMINISCENCES OF A PHOTOGRAPHIC VISIT TO GERMANY.

BY JOHN AMBLER.*

As there was no paper announced to be read this evening, a short account of a visit I paid to Germany in August and September, 1873, with Mr. McLachlan, may not prove uninteresting to the members of this Society.

Doubtless most of you have seen Mr. McLachlan's great group of the Royal Family of England, which is now exhibiting at the Royal Institution in this city. It was in connection with this picture that we went to Germany, as the group includes Her Majesty the Queen, her sons and daughters, and their wives and husbands, as well as some of their children—in all, twenty-two figures. Separate photographs of each of these royal personages had to be taken. A design of the group was, in the first instance, shown to Her Majesty, through the Earl of Derby, and Lord Winmarleigh, with which Her Majesty was greatly pleased. She was the first to be photographed, and then graciously gave Mr. McLachlan letters of introduction to each of her children.

The photographing of these royal personages necessitated visits to Windsor, Balmoral, Osborne, Buckingham, Inverary, Marlborough House, Berlin, Potsdam, Darmstadt, and Seeheim—to Berlin and Potsdam to photograph our Princess Royal and her husband, H.I.I. the Crown Prince of Germany, and their eldest son and daughter; and to Darmstadt and Seeheim to photograph H.R.H. (the late) Princess Alice and her husband, the Grand Duke of Hesse, and their eldest daughter, Princess Victoria. Mr. McLachlan had been to Germany the year previously to photograph some of these members of the Royal Family, but in order to photograph the remaining members this second visit had to be made.

To make a group of twenty-two ordinary individuals is a comparatively easy matter, but a group of twenty-two royal personages is another affair altogether—the former being so easy of access, but in the latter case you had to pass General this, Count that, and Major someone else, just like passing so many sentries. With your permission I will here quote a few words from an article on Mr. McLachlan's picture, which appeared in the *Manchester City News* of January 25th last. The writer says:—

“A great man about the Court at Windsor Castle, with the most kindly intentions, advised Mr. McLachlan to abandon his project. ‘You are intent,’ he said, ‘upon making a group of the Royal Family. Your design is a beautiful one, and I should like to see it carried out; but I wish to save you a world of misery and trouble. The thing is simply impossible. When Prince Albert was living it might have been practicable, for he loved art and artists. When he lived Sir Noel Paton was commissioned to paint a group of nine members of the Royal Family. For two years he worked at Cumberland Lodge, but such was the worry he had in trying to get sittings that it ended in brain fever, and he abandoned the work. Then Mr. Lake Price was commissioned to paint a group, but he caught brain fever from the same cause as Sir Noel Paton, and he abandoned the work. And now you come, and you want to paint a group, not of nine members, but of twenty-two, scattered all over Europe. Do you expect, after the failure of your distinguished predecessors, that you will succeed?’”

With these preliminary remarks I will proceed. As neither Mr. McLachlan nor myself were very conversant with the German language, the best thing to do was to have the apparatus and chemicals as complete and as safely as possible, so that we should have little or nothing to trouble our German chemists for. No expense was spared in this respect. The luggage consisted of five well-made boxes, each divided into compartments, and each compart-

ment lined with thick felt. One box contained eight of Dallmeyer's lenses, including a pair of his 3b cabinet lenses. Another box contained a 12 by 12 bellows camera, so arranged that by use of the repeating back four cabinet portraits could be taken on a 12 by 10 plate, and four cartes on a 7 by 9 plate. The negative bath solutions were in strong bottles packed in compartments in the centre of the remaining boxes. Although they had to stand the frightful knocking about which they received at the hands of the officials at the different stations during our two months' stay in the Fatherland, we came back without an article broken.

Leaving Dover shortly after eleven one night, after a pleasant sail we arrived at the Belgian port of Ostend about three o'clock in the morning, as day was breaking. Our trouble commenced here; for, through some stupid rule, the officials would not let a studio camera-stand which we had brought accompany us with the rest of our luggage, although we entreated these officials ever so much. No; it must follow by the luggage train! We received it a week afterwards.

Our destination was Seeheim Castle, about twelve miles from Darmstadt, where the late Princess Alice was staying for a few weeks with her children, Prince Louis (the present Grand Duke of Hesse) being in England at the autumn manœuvres.

Brussels was reached at 7:30 a.m., and as the train for Cologne did not start until 9:30, we had a hasty look round the city; but, before doing so, the “inner man” was attended to by our enjoying a hearty breakfast. On our arrival at Cologne, our luggage had to be overhauled by the Custom House authorities. This was not a difficult matter, as the collodion, &c., in the boxes was easily got at.

The German railway officials are an impudent race, for after having given one of them a substantial “tip” to see the luggage to the train, another fellow pestered us for half-a-crown. Yes! actually named the figure. “What for?” we exclaimed! “For telling the other man to look after the luggage!” was the calm reply. They seem to think that Englishmen are made of money.

As we were in a hurry to get to our destination we had only a ten minutes' glance at Cologne. After leaving the latter city, the railway runs close to the Rhine for many miles until you reach Coblenz, and a charming ride it is. I had heard of the beauties of the Rhine, but its splendour surpassed my expectations. We arrived at Darmstadt at ten o'clock at night thoroughly knocked up, not having had a wink of sleep since leaving Manchester; so we were glad to get to bed at a very comfortable hotel.

The next day we took train for Bickenbach, a village station about twelve miles from Darmstadt. There were only two old men who acted as porters, so it was no easy matter to inform them what we wanted. I, fortunately, had an English-German conversation book in my pocket; so, after glancing at its pages a moment, I managed to make one of the old men understand that we wanted a conveyance to take our luggage to Seeheim Schloss, for he very soon brought an odd-looking cart and horse which carried our luggage to the castle—a distance of three miles—while we walked behind. A terrific thunderstorm raged all the way, so that we were drenched to the skin, as we, unfortunately, had left our umbrellas in the railway carriage at Mayence, where we had to change carriages unexpectedly, and, therefore, hurriedly.

After arranging a few preliminaries, we made the best of our way from the castle to the village hotel at Seeheim. We stayed at this hotel for a few weeks, so you may be sure we had a quiet time of it, we two being the only persons who spoke English. If we wanted to order dinner, the conversation book before mentioned would be opened, and whilst the waiter ran his finger down the German column of dishes, I would run mine down the corresponding English column, and when the name of the desired

* Read before the Manchester Photographic Society.

dish was arrived at, the finger would stop, and I would give the waiter a nod.

During these few weeks, several photographs of the Princess Alice and family were taken. Some may wonder why we should have to stay so long in order to take a few photographs. This is easily understood when one considers the numerous engagements which royalty have, and also when we bear in mind the fact which photographers know too well, viz., the difficulty of getting a certain pose, effect of light, and, above all, a certain expression combined in a photograph. All these effects must be obtained with each figure in order to form one harmonious group, when the combination of photographs came to be put together, from which composition the black and white oil painting had to be made.

Her Highness had only a few months previously received a most severe shock by the death of her beautiful boy, Prince Fritz, whom she accidentally let fall through the window of the palace at Darmstadt. This will account for the sorrowful expression Her Highness has in the group.

One evening we took train from Bickenbach to Darmstadt for a bottle of distilled water, and after obtaining the precious article at the chemist's, we made our way back to the railway station; but discovered that the porter had told us the wrong time the last train left for Bickenbach—it had gone! As we had an appointment with Her Highness for the next morning, we were compelled to get back somehow; so we hired a carriage and pair (if you want to drive at anything like a decent speed in Germany it is no use having only one horse in your conveyance). It was then ten o'clock, so speed was a necessity, or we should find it a difficult matter to obtain admittance to our village hotel. It was after midnight, however, ere we reached our destination, having travelled through a "fores: deep and gloomy" for several miles, the driver walking in front with the lamp to guide the way, as it was very dark, and the road exceedingly bad. Before we could arouse our host we had to ring a big bell in front of the hotel for some time, making an awful din. The bottle of water cost about 18s.

(To be continued.)

PHOTO-TYPOGRAPHY.

BY CAPT. J. WATERHOUSE, B.SC.*

THE object of the photo-typographic processes is to obtain a surface block by photographic agency, that may be set up with type in the same way as woodcut, stereotyped, or electrotyped blocks, and be printed in the ordinary printing press. The process offers great advantages in the rapidity with which the blocks may be made and printed off in large numbers. Up to the present time no entirely satisfactory method has been discovered for printing subjects in half-tones in this way, though Mr. Duncan Dallas has produced some very promising results. The processes are, therefore, almost entirely limited to the reproduction of subjects in line or dot alone. The operations in this branch of photographic reproduction are based upon exactly the same principles as the photo-engraving processes just considered, and in some of them the only difference is the substitution of a positive cliché for a negative, or *vice versa*.

The existing processes may be divided into three classes. 1st. Those in which a mould is made from a relief in swollen gelatine. 2nd. Those in which the image is obtained in asphaltum or gelatine on a metal plate and bitten in. 3rd. Those in which an image in a waxy and resinous ink is obtained by the methods described under the head of photo-zincography, then transferred to a metal plate and bitten in.

Moulding Processes.—Of the first class several methods

have been introduced from time to time, but they are all on the same principle, and are modifications of Pretsch's and Poitevin's processes already described, differing, as a rule, merely in technicalities, which, being trade secrets, have not been fully published.

The following method is a typical one. A glass plate or other suitable surface is coated with a mixture of gelatine and bichromate of potash, and, when dry, exposed to light under a negative. After this, it is immersed in cold water till the parts unaltered by the light, which represent the whites of the original drawing, swell up to the required height, leaving the lines quite sunk. The plate is then removed from the water and, the superfluous moisture having been carefully blotted off, is ready to have a cast made from it.

This may be done in two ways: first, by metallising the gelatine surface, either by means of plumbago or bronze powder, or by reducing silver upon it by applying a solution of nitrate of silver followed by treatment with a solution of pyrogallic acid, or of phosphorus in bisulphide of carbon. The gelatine relief then receives a thin deposit of copper in the usual way. The thin copper electrotype is backed up with type metal, planed, and mounted on a wooden block, so as to be of the height of type. This method gives the finest results, but takes time.

The second method is to take a cast of the gelatine relief in type-metal. A cast in plaster, wax, &c., must first be taken from the gelatine, a second cast in plaster is made from this, and then stereotyped in the usual manner. This method is quicker than the last, but the results are coarser.

These processes are now largely used for illustrations in books and newspapers, but, so far as I know, have not been regularly applied to the reproduction of maps.

Etching Processes.—The processes in the second class, in which a metal plate on which the image has been obtained on a sensitive coating of asphaltum or gelatine is bitten in with an etching liquid, though capable of giving very perfect result, are not, I believe, so much used as the other methods which are quicker and more simple.

A photographic image is impressed from a reversed negative on a copper or zinc plate prepared as in the Berlin engraving process already described, and, after development with olive oil and turpentine, is bitten in so as to yield an image in sufficiently high relief for surface printing, the precaution being taken of protecting the finest parts of the work, as soon as they are sufficiently bitten, by covering them with stopping-out varnish.

If the sensitive surface is chromated gelatine, the soluble gelatine may be removed, or not, but the etching fluid must be such that it will not dissolve or remove the gelatine from the surface of the plate—solutions of perchloride of iron, bichloride of platinum, nitrate of silver in alcohol, bichromate of ammonia in dilute sulphuric acid, are some of the most suitable mordants for the purpose. In any case, the full amount of relief cannot be obtained by biting through the gelatine at one operation. After the first biting-in the gelatine film must be removed, and the lines protected from the further action of the etching fluid.

Gillotage.—The last class, in which a photographic transfer in resinous ink is made on a metal plate, and then bitten in, comprises the simplest and most largely used of these processes.

The process generally employed is substantially the same as Gillot's "paniconography," now commonly called Gillotage, which is largely used for illustrated papers and various other purposes.

A polished zinc plate, which has been strongly varnished at the back to protect it from the acid in the subsequent operations, receives a transfer in greasy ink, either from an engraved copper plate, a lithographic drawing on paper, or a photo-transfer print prepared as for photozincography.

* Journal of the Asiatic Society of Bengal.

The plate is then etched in the usual way and rolled up with a varnish ink containing a large proportion of resinous matter; it is then dusted with powdered resin, which sticks to the lines, and renders them more capable of resisting the acid, the superfluous resin is brushed off, and the plate is gently heated.

The edges of the plate and the large white spaces are covered with shellac varnish, and when the varnish is thoroughly dry, the plate is plunged into a trough containing very weak dilute nitric acid, kept in constant motion, and is left until the finest parts are sufficiently bitten, which generally takes about a quarter of an hour; it is then taken out of the trough, washed, dried, and placed on a sort of grating over a charcoal fire. Under the influence of the heat, the coating of ink and resin on the lines, being gently softened, flows down and protects the sides of the hollows formed by the first biting, filling up the spaces where the lines are very close. As soon as this effect is produced the plate is allowed to cool, and then inked with a lithographic roller, as if a proof was going to be pulled. It is again dusted with powdered resin, and is then ready for a second biting in, which is to attack the parts somewhat lighter, and therefore may be effected with stronger acid.

The operations of inking, dusting with resin, heating, and biting with acid are repeated several times till the plate presents only a uniform black colour. Then the plate is bitten with strong dilute acid, which bites out the parts to be left completely white. The large whites, which have been covered all along with a strong shellac varnish, are then cut out with a saw, and the plate is ready to be mounted on a wooden or leaden block for printing. These plates usually require considerable touching up to take off the ragged edges of the lines caused by the spreading of the ink, though this may also be done by repeating the inking and biting in, so as to remove the steps formed by the successive bitings.

This process has been applied at the Imprimerie Nationale, Paris, for producing large geological maps, but the special precautions that had to be taken in "overlying" the plates in the press so as to print properly were very tedious, and must have largely increased the expense and lessened the use of the process. Messrs. Yves and Barret, of Paris, are said to use it largely for reproducing maps and engineers' plans, &c.

(To be continued.)

ON THE FADING OF PHOTOGRAPHS AND ITS REMEDY.

BY A. HESLER.*

A SHORT time ago I was looking over a lot of my old photographs that were printed eighteen and twenty years ago; some were in albums, others laid away in bundles among clothing, and in trunks and drawers, and was I surprised at their remarkable preservation, the deep blacks and half-tones being as clear and perfect as when first made; whereas some of a quite recent date showed unmistakable signs of yellow fading. Upon investigating the matter, I find that the old perfect prints were toned with platinum and gold (two parts platinum to one of gold), and cleared in fresh hypo, made fresh each day. The washing was done as follows: The rose of a common sprinkling-pot was attached to the hydrant-faucet that was placed over the sink; under this a large sheet of double-thick glass was placed, on which the sheets of prints were placed (at that time we did not trim cards or cabinet cards until after washing and drying), the water let on which fell in a gentle shower over the entire surface. While this was going on, a broad bristle brush was passed gently over each side of the print, which was then passed to a tray of clean water. Thus in twenty minutes to

half an hour, twenty to forty sheets of prints were passed through four to six changes of water, and ready to hang up and dry. I believe this, for all prints larger than cards, to be the most thorough and rapid way of washing prints; only by the brush I would substitute a roller similar to that used by the printers for inking type (unless hot water is used, the same composition used by printers would answer very well); or at the rubber stores, a piece of small, thick, rubber hose could be got, through which a hard, round stick could be crowded, and a frame attached. This can be handled in one hand while the prints are changed with the other. Now while this thorough and short washing had its good effect, I believe the permanence of the prints more due to the platinum toning than anything else. I used it at the time because I thought it improved the tones of the pictures, but am now satisfied it has the good effect of preventing fading. At that time the chloride of platinum was not kept by the dealers, and I had to make it for my own use, and supplied it to a few, who thought it of advantage to use it. The metal dissolves in *aqua regia*, the same as gold, but much slower, and requires some considerable heat to dissolve, but otherwise treat the same as gold.

LIGHT, AND ITS WORK IN ABSORPTION.

BY CAPT. W. DE W. ABNEY, R.E., F.R.S.*

HAVING now dwelt upon the absorption by certain bodies, and seen that the carried energy is converted into heat, we will now turn our attention to cases of absorption in which the energy conveyed by radiation does another form of work.

Let me show you a preliminary experiment. I have in this cell some slightly acidified water, and in it I place the ends of two wires, one of which is connected with the zinc, and the other is ready to be connected with the platinum, which are immersed in this jar of acid. You see the magnified image of the cell and its contents on the screen. I now touch the platinum with the wire, and you see we have a shower of gas given off at each wire. If I collected these gases, I should find them to be oxygen and hydrogen, the components of water, the heat of the recombination of which, being directed on a lime cylinder, furnishes one source of light for the lantern. Here we have a something doing work of another form—splitting up a liquid into its chemical components. This class of work we call chemical action. We should find that in order to do this work in our glass cell, work was being performed in the jar—that a certain quantity of zinc was being eaten away to form sulphate of zinc to enable this work to be performed. In other words, the energy called into play by chemical action in the jar was carried along by a something in the wires (which, be it remarked, remain unchanged) to cause chemical action in the water. That something in the wires we have strong evidence is the same medium which we have already spoken about, and the transmission of energy is caused by a wave motion in it. To produce our electric light, we have a similar consumption of zinc, but in this case, instead of chemical action taking place, we have the energy carried along the wires doing work in heating the particles of the ends of the carbon rods.

Now, ordinary radiation, in some instances, can do the same class of work. I have here a plate which is coated with collodion containing bromide of silver.—a molecule of which is a combination of two atoms of bromine with two atoms of silver. Note the colour—it is a yellowish tint by transmitted light; hence it ought to absorb the blue and violet. You will see that it does to a certain extent when I place it in the spectrum. Now, one atom of bromine is not in the same way knit to the atoms of silver in the molecule as are the others. One is more loosely com-

* *Practical Photographer.*

* Continued from page 104.

bined than the other, probably being more distant from the whole than the other. This atom might therefore be shaken off if proper force were applied. A boy pulling at the rope of a bell, if he only pulls at proper intervals of time, will be able to swing the bell, all the small applications of force being collected together as it swings. So with our wave of light, the continuous application of the energy of certain of the waves is able to cause the whole molecule of silver bromide to swing about so violently that the loose atom is thrown off from it, more particularly if we suppose that part of the energy is expended in giving an internal motion to the molecule. This becomes perceptible to the eye by change of colour after a time, though it takes place on some of the molecules with a very short impact. In this plate, part of which has been exposed for a short time to the light, you will see that the colour is changed.

I will now demonstrate to you that the change takes place with a short impact which is altogether imperceptible to the eye. Behind this etching on glass I have placed a plate covered with silver bromide, and expose the latter through the former to the blue rays of the spectrum. I now shield the lamp with red glass, which is permissible, since the red rays pass through the film and can do no work on it, and place the plate in a cell containing a reducing agent, which more readily reduces to the metallic state the silver bromide acted upon by light than it does the bromide, which has been shielded from it. I throw the outline of the plate on the screen, and you note the image appearing. The dark parts which appear are those which have been acted upon by light, whilst the parts which remain of the original colour are those which have not been exposed to the light, which the bromide absorbs.

This, then, is the rationale of photographic processes. It is simply the transference of energy carried by the light radiated or reflected from any object to perform chemical work in the molecules of the silver compound. I dissolve away all the unaltered bromide, and show the picture on the screen.

The same silver compound may also be produced of a different colour. Here we have it in its blue state. It now absorbs both red and yellow, and the radiations producing these colours must evidently do some kind of work. They produce the same effect as the other colours—that is, these radiations produce chemical decomposition.

I might show you, if I had time, many other compounds which absorb light, and which are acted upon in the same manner. For instance, this solution of ferric oxalate is easily acted upon, and carbonic anhydride is liberated.

Another very striking experiment is one in which we cause the union of two gases by the action of radiation. In this thin glass bulb we have two gases enclosed, viz., hydrogen and chlorine. The former is colourless, the latter is of a green tint, as its very name indicates. Equal volumes of these gases can combine to form hydrochloric acid, and the combination is effected with explosive force if intense light fall on them when they are mixed together in the right proportions, as they are in this bulb.

We can cause a sufficient intensity of light by the following arrangement:—E is the electric wire, L the lens of the lantern, B the glass bulb containing the gases held in the clamp C, M a silvered mirror held on a stand of short focus, into which B is inserted. We find the focus

by using a strip of paper, cover up the lens L, and put B *in situ*. In the front, L, I hold red glass, and uncover it, and you see that the bulb with its gases remains there in perfect quietude. I re-cover the lens, substitute a piece of

blue glass, and again uncover the lens, and we have a terrific report, and the glass of B shivered into a thousand pieces. The hydrogen and chlorine molecules have been so swung together by the blue radiations that they combine with the result we saw and heard.

Here we have two coloured stuffs which have been exposed to light, and you see how they have been changed simply by light and nothing else; and in all cases without exception, I may say, the change has been effected by the rays of light absorbed.

Here we have abundant proof, then, that energy from a luminous body and carried by the radiation may be expended as the work known as chemical action. The expenditure as heat is a separation of molecule from molecule, whilst that as chemical action is a disintegration or integration of the molecules themselves.

I will demonstrate to you how rapidly this chemical action can be produced. This is a photograph of the spark of an electric machine taken by its own light. The length of that spark was four inches, and on the plate it was three inches. Its passage is exceedingly rapid; so rapid, indeed, that it is with the greatest difficulty that it can be measured; it probably jumped between the poles in about 1-6,000th of a second. The spark itself may be looked on as a ball of heated atmosphere about 1-100th of an inch in diameter, passing at this rate across the interval, and the passage of the image of this ball across the portion of the plate on which it impresses itself is only illuminated about 1-2,600,000th of a second; yet in that short interval of time a succession of 270,000,000 blue waves have impinged on the plate, which have been more than sufficient to effect the chemical change on some of the molecules. The energy conveyed by the radiation from the spark was large; that is, the waves were of great amplitude, by which I mean that, taking the simile of a sea wave, the difference of level between the trough and the crest must have been much greater than would be the case of the blue light radiated from our electric light.

These coloured stuffs which I have shown you as being altered by radiation are examples illustrating a phenomenon in which every one possesses an interest. The bleaching produced, and the rapidity with which chemical change can be produced, as exemplified by that spark photograph, teach us a lesson in regard to vision. Within the eye we have a dyed tissue of a purple colour, which bleaches by the action of light. How rapidly it completely bleaches we do not know, but that it commences to bleach instantaneously we may well believe. In the eye we have a lens which forms the image on this dyed tissue, and we see the image because of the partial bleaching of this tissue. When we shut our eyes, go into darkness, or alter the position of the image, the tissue re-dyes itself automatically, and is ready to receive another image. Vision is therefore a truly photographic process, and is produced by the energy in the waves performing the work of chemical decomposition.

We have now shown you how the energy carried by light is absorbed, and I would, before I conclude, like to show you how the natural colour of bodies is dependent on absorption.

I hold up the red cover of this book in the spectrum, and pass it through it. See, it is beautifully illuminated in the red, and it becomes black in the rest of the spectrum. Here I have a bouquet of flowers which I pass through the spectrum, and we see how the different colours are gradually illuminated, and darkened. Mark how the red flowers spring out in the red part of the spectrum, and appear black in the blue, whilst the blue flowers spring into visibility in the blue, and become dark in the yellow and red.

The white camelia which we have, takes the hue of the colour in which it is placed, and changes like a chameleon, and yet it is white.

PRESERVING SENSITIVE PAPER.—AN EFFICIENT METHOD.

THERE is no object to the silver printer of greater importance, perhaps, than the preservation of albumenized paper in good condition for a considerable time after it has been made sensitive. That the thing is possible, is proved by the fact that there is in the market for sale commercially ready sensitized albumenized paper of good quality; but this is probably too costly for the purposes of professional photographers. Many formulæ have been published for conferring keeping powers upon the sensitized paper, and many of these have been confessedly efficient; but there have been drawbacks which deprived them of much of their value. The early method of using a chloride of calcium case seems to have passed quite out of use. Here the preservative agency appeared to have been an atmosphere of chlorine, which slowly converted the free nitrate into chloride of silver. The free nitrate is manifestly the deteriorating agent, but paper containing chloride of silver only prints slowly, and the image lacks vigour. Paper which had long been kept in the chloride of calcium box rarely gave satisfactory prints, hence it fell into disuse.

The favourite agent in preserving sensitive paper of late years has been citric acid applied in some form, being either added to the silver bath, or applied in a separate solution. That it possesses valuable preservative qualities cannot be doubted, but it presents the inconvenient drawback of materially interfering with the process of toning the print. It almost invariably makes the toning slow and tedious, and sometimes almost impossible. This is a fatal objection to any method, as anything which interferes with the perfection of toning is out of the pale of acceptance. There are two communications in our recently-issued YEAR-BOOK, both giving new methods of applying citric acid as a preservative, and both strongly commended by intelligent and trustworthy correspondents.

We are now about to describe another method recently communicated to us by Mr. Valentine Blanchard, who has for some time tested it in his own practice with the most complete success. The paper treated keeps in perfect condition, he states, for some weeks, and there is no difficulty or imperfection in the toning whatever. Those to whom he has communicated his method privately, fully confirm his experience; hence, we believe, we confer on our readers a boon of considerable value in publishing the details. The silver bath is made at the outset a little stronger than usual. Mr. Blanchard's usual strength was forty grains of nitrate of silver to the ounce of water. Now he uses fifty grains of the silver salt. To this he adds of a

saturated solution of citric acid in water, ten drops to each ounce of nitrate of silver used. The result is a deposit of citrate of silver in the solution. He now adds to the silver bath, nitric acid, drop by drop, until all the citrate of silver which had been thrown down is re-dissolved. This constitutes the printing bath ready for use. The paper is floated as usual, and, after the usual draining, is laid flat, and blotted off before it is hung up to dry. The paper so treated keeps well, prints well, and tones well, being, in fact, in no wise injured by the citric acid, whilst gaining so immensely in keeping qualities. The rich depth and fine tone of Mr. Blanchard's large prints—produced chiefly from thin negatives—are well known to most photographers.

"I do not profess to theorize on the subject," Mr. Blanchard remarked, on communicating the method in question; "I merely state the facts based on well-tested experience." These facts are really of more interest to practical photographers than a thousand ingenious and perfectly congruous and consistent theories. It may be interesting, however, to glance for a moment at what occurs. The solution of nitrate of silver, when first mixed, is manifestly neutral, or even slightly on the alkaline side of neutrality; if it were not so, the precipitate of citrate of silver would not be formed on adding citric acid. It is a fact worth noting that the nitrate of silver now in commerce is almost invariably neutral, whilst at one time, a few years ago, it generally contained free nitric acid. On adding nitric acid to the solution, in which a precipitate of citrate of silver is present, the precipitate is dissolved, nitrate of silver being formed, and citric acid set free. Hence the solution consists simply of nitrate of silver in solution with free citric acid present. In this state it seems to possess the preservative quality required, without exercising the detrimental action on the toning operation. But there is another important fact to note. Mr. Blanchard removes the excess of free silver solution commonly left on the paper and regarded by many as essential to vigorous prints. In the two communications in our recent YEAR-BOOK, to which we have referred, both Mr. Willis and Mr. Colquhoun lay stress upon a similar operation; they also remove the excess of silver solution. Now we have little hesitation in saying that the keeping qualities of the paper would be greatly improved by this removal of silver solution, even without the addition of citric acid. That the free nitrate of silver is the chief cause of the discolouration of the paper, we think there can be little doubt. But that when it is removed an important element of vigour in the print is removed also, is matter of equally little doubt. To meet this difficulty the citric is present, and supplies an important element of printing vigour. In our early experiments with collodio-chloride of silver printing we met with a difficulty, the solution of which is illustrative here. We obtained vigour in printing on paper by using an emulsion with free nitrate of silver. In working with the same emulsion on opal glass, the free nitrate crystallized on the film, and eventually the image was covered with pinholes. In this emergency Mr. Swan and Mr. Bovey, nearly simultaneously, suggested the use of citric acid in the collodio-chloride. This at once met the difficulty: vigour and depth were obtained without free nitrate of silver.

Perhaps it may be desirable to add, that we have not heard of cases of failure with the method first published in these pages some years ago. We refer to the use of blotting-paper saturated with a solution of carbonate of soda. This is a simple method still practised by many, and generally, we believe, with success.

NOTES AND QUERIES.

ONE of the primary aims of photographic journals has been to afford a means of inter-communication between photographers for the purpose of exchanging ideas and information. In the early volumes of the PHOTOGRAPHIC

NEWS, besides the publication of articles, papers, reports, news, correspondence, and answers to correspondents, a space was devoted to "Notes and Queries," in which difficulties and abnormal experiences could be stated, and answers and explanations offered by any whose experience aided in the solution of such difficulties. This department was often of great value, and, by the courtesy of many experienced correspondents, the Editor was relieved of the duty of answering many querists in the column devoted to that purpose. In process of time, as the art fell very much into beaten tracks, and in the absence of essentially new processes prompting enquiries, this department fell out of use, and eventually even the heading was withdrawn, letters containing subjects for discussion being published under the heading of "Correspondence," and queries answered by the Editor in "Answers to Correspondents."

It has recently been suggested by some esteemed readers that the revival of this column would at the present time be very opportune and useful. Novelties in photography are rife at present. There are many new processes of great importance demanding attention; and novices greatly need the aid of their more experienced brethren in combating difficulties arising in practice. In emulsion photography, for instance, which promises to supersede—at least, to a great extent—the wet collodion process, novel points are continually arising, which the interchange of experience alone can satisfactorily settle. And still more frequently there are difficulties which beset the novice, which only the courtesy of their more experienced brethren can help them in. There will be no lack of querists, we know; and we believe we may trust to the generous instincts of a large body of able photographers to supply information on this and many other points requiring elucidation at the present time.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY IN THE DEPARTMENT OF THE MINISTER OF THE INTERIOR OF FRANCE—ART RENDERED MECHANICAL BY PHOTOGRAPHY—PHOTOGRAPHIC PAPER AND THE COMMERCIAL TREATIES—GENERAL NEWS.

Photography in the Ministry of the Interior.—The officials of the various Government Departments in France are rather celebrated for the tenacity with which they adhere to routine. Lately, however, in several instances, praiseworthy attempts have been made to abolish the old and time-honoured red-tape, and to take advantage of modern discovery to effect improvements in the service of the State. The most recent example has occurred in the Department of the Ministry of the Interior, where the postal and telegraphic services, which are so much behind those of other countries, and more especially those of England, are about to undergo modifications quite necessary to enable them to meet existing requirements. It is by no means surprising that in this path of progress photography should hold a prominent place. The PHOTOGRAPHIC NEWS has already had occasion to chronicle what has been effected at the Bank of France as regards new applications of photography; and I have now just heard of another important improvement that has been carried out in the organization of another public office; this is the establishment of a photographic studio in connection with the Department of Cross-Roads. Up to the present, the road-map of France has been from necessity most incomplete, but now the following plan has been adopted for remedying this great inconvenience. It is well known that excellent maps exist in the Staff office of the War Department, and it was thought that they might well serve for the groundwork of the proposed map, but, unfortunately, they have been drawn up solely for military purposes; besides which, the War Office does not recognise officially the designs and transactions of the Department of Roads, which is a branch of the Home

Office. The two departments, therefore, had to be moved, and induced to render each other mutual assistance—not by any means so easy in practice as might be thought. Photography, however, which has already cut so many Gordian knots, was equal to the task of severing the present entanglement. The map of the military staff had been drawn on a scale of 1 : 800 000, which does not easily admit of the reduction and corrections necessary in the case of maps intended for Civil purposes. By means, however, of the newly-established photographic department, a map can be produced of any required dimensions; this is then handed over to the draughtsman and engraver. The whole map, when completed, will be in sheets, and these are distributed among the different road-surveyors in the provinces, who will enter on them all the changes that have taken place in the surface of the country—where new roads have been made, where old ones have been closed, or where woods have been cut down. What the military surveyors have not done, because it was not their business, will be carried out, thanks to its special opportunities, by a Civil department of the State. In this way the map of France, which was so defective at the time of the war, and which in some cases was the cause of military disaster, will become a trophy equal in merit to the one raised by the German military engineers. This, then, is another point saved by photography in the service of the State, in addition to all the others that it has already secured. I have recently had occasion to pay a visit to this newly-established photographic department, and I am glad to be able to give a highly favourable report of its organization and management. It is under the direction of an able and intelligent man, who devotes all his energies and talent to the fulfilment of duties that must continually increase in importance. There are still a few trivial difficulties that have to be overcome, due to the punctiliousness of the military staff, which is very jealous of its powers, and does not like its functions to be in any way interfered with. But these prejudices, it is to be hoped, will soon be conquered.

Spurious Oil-Paintings Reproduced by Photography.—Under certain circumstances photography may with advantage be employed as an auxiliary of the fine arts; but there are others where all true artists would resent its intervention as an intrusion. Among the latter must be classed some pictures that have recently been produced by painting in oil on the back of photographs rendered transparent by means of Canada balsam, or some such method; these photographs are then passed through the press, and are thus made to resemble oil-paintings. Some speculators are busy exhibiting these pictures in Paris in the hopes of getting up a company for their manufacture and sale on a large scale. Pictures thus reproduced by photography are to be palmed off especially for the decoration of churches, and thus a mechanical imitation of Rubens or Van Dyck, Titian or Raphael, will take its place as an ecclesiastical altar-piece. Good-bye, then, to all the tradition of art, to all enthusiasm for the old masters, to all encouragement of living artists, if such forgeries as these are to prevail. Photography would be degraded in such a service, and deserve nothing but condemnation. In reproducing what it beholds, or as the handmaiden of art, photography can render great services; but if it be employed in supporting mechanical frauds, in imposing upon ignorance, or in promoting bad taste, it will be scouted by all who possess a love for the beautiful.

Photography and the Treaties of Commerce.—The photographic public is being seriously disturbed by the discussion on the commercial treaties, more especially as regards the terms on which paper will be allowed to enter France. At present we are supplied with albumenized paper from Germany and Austria, which is eagerly sought for on account of its excellent quality; but the paper itself is all manufactured here at Rives, near Grenoble. When, therefore, it comes back to us coated with

albumen, it crosses the frontier for the second time. The new protective tariff will be much more severe, and will have the necessary consequence of raising the prices of all kinds of paper used in photography. It is, therefore, now proposed to meet the difficulty by establishing a manufactory in France for the albumenization of these papers. This ought to possess as good laying powers here as anywhere else; and even if that should not be found to be the case, the newly-discovered processes of obtaining albumen will easily enable us to overcome such an obstacle. This project of carrying out completely in France the manufacture of albumenized paper, and thus rendering ourselves independent of foreigners, meets with the approval of all our photographers, especially at the present time, when the new protectionist laws threaten to still further augment the inconvenience of our situation, already rendered sufficiently annoying by the fact that paper manufactured in France is sent abroad, and then returned burthened with double duties.

Miscellaneous News.—The disagreement between the owners of certain photographic processes denominated "extra rapid" causes a considerable amount of amusement to a numerous class of persons who have purchased the licence for working the said processes. M. Boissonas, as he has already stated in the PHOTOGRAPHIC NEWS, has dissolved his partnership with M. Klary, and it is probably in consequence of this difference that the latter gentleman is about to establish himself at Paris, where, according to general report, he has taken the house of M. Bertall, a large photographic establishment near the Madeleine. Apropos of the so-called extra-rapid or lightning processes, and the fuss that is being made about them, it may not be out of place to point out that an Englishman, Colonel Stuart Wortley, was the first, in February 1863, to recommend the use of copper acetate in the developer; that skilful photographer, M. Klassen, has recently recalled this fact to our recollection.

In my last letter I mentioned the process of M. Germeuil-Bonnaud for photographing in colours. A joint stock company has just been formed for working this process.

As regards new books relating to our art, I have to mention the publication of *L'Annuaire Photographique* for 1879, of M. Fabre, which makes its appearance rather late; and a work just sent to press to be edited by M. Gauthier-Villars under the title *La Photographie et l'Archéologie*. Judging by the name, we shall have a most interesting book.

A NEW TONING PROCESS FOR LANTERN SLIDES AND TRANSPARENCIES.

BY WILLIAM BROOKS.

BEFORE the lantern season closes, I wish to describe a system of toning lantern slides and transparencies whereby any tone that may be desired is easily obtainable. It is a process that I have worked for the past twelve months, so I have had some little experience with it. It is one of those processes, like many others, in which totally different effects are produced by using the chemicals employed in a somewhat different manner; and I have not introduced into the process any new chemicals, but simply those which have been known to photographers for many years past.

Some may not altogether agree with me in calling it a new toning process, but I think I am fully justified in so doing, as I produce results that have hitherto not been obtained, although the same toning agent has been employed. I consider the method I am about to describe a most valuable one, and I do not think any one will fail to understand it so as to work it successfully.

As this article is intended more as a treatise for the production of magic lantern slides of the highest class, I will first state the class of transparency that is requisite for the purpose, as I have no doubt that many will read this who have never made a magic lantern slide, and may be tempted

to do so if I make everything as plain as possible, which I will endeavour to do.

A good slide must possess the following qualities when examined: the deep shadows must be intense (that is, only the extreme shadows), not necessarily opaque; the high lights of the picture must be *bare* glass; and all the gradations from high light to deep shade intervening; and when the slide, before it is mounted, is laid down on a piece of white paper (film side downwards) it almost has the appearance of a print—rather duller. Should the high lights appear foggy, it is sure to have a foggy appearance on the screen; should the class of slide in question be of an intense kind, it may be rectified, as will be seen further on; but should it be of a thin and weak character, it is best not to waste time over it, but make another.

I have often wondered why the manufacturers of lantern slides do not make their slides of different intensity, suitable for both oil and lime light; for it is a well-known fact that a slide that gives a good image with an oil lamp is perfectly useless for lime light; and, on the other hand, the slide that is suitable for the lime light gives a very dark, heavy image with the oil lamp. I have found in practice, that should a slide be found too weak, if the lens on the lantern is an ordinary portrait combination, furnished with Waterhouse diaphragms, by inserting one of the stops it sharpens the image, and, at the same time, reduces the light. I have seen slides treated in this way that have left nothing to be desired. I think this system, where practicable, better than lowering the light. Unless the slides are of the character named, the best results must not be expected. It is an old adage that what is worth doing at all, is worth doing well; and I am sure it can be applied to all photographic productions.

The system that I adopt is the collodion washed emulsion process. I find it best to use an emulsion containing only a bromide; an iodide must be avoided. I have occasionally used an emulsion containing a chloride, but, on the whole, I prefer the one containing a bromide only. For lantern slides it is well not to have the emulsion too thick; a little thinner emulsion than for ordinary negative work is best, but the coating of the plate must not be hurried. By using it thinner than usual, a finer result (for this class of work) is obtained for transparencies for window decorations, &c.; where a more intense image is required, it can be used thicker with advantage.

I use the best polished flatted crown glass of medium substance, rejecting all the thick pieces. I soak them in a dilute solution of mineral acid—whichever is at hand: either sulphuric, nitric, or hydrochloric acid—using about one ounce of acid to the pint of water. I allow them to remain in this solution for about half an hour, and then well stream each one separately under the tap, and polish with a little methylated spirit and chamois leather. To prevent the film from slipping, edge with a solution of india-rubber in benzole, about one eighth of an inch all round. To save time, the plates need be polished on one side only. They are coated with the emulsion as with ordinary collodion, taking care not to hurry this operation, especially in cold weather. The plates are then set to dry, and will be ready for use in an hour or two at an ordinary temperature of 60°.

I must not omit to mention that a plate coated with a preservative is unsuitable for this process, it being difficult to tone.

It is very seldom the negatives from which slides have to be made are of the right size to permit of the transparency being made by contact. If it can be done (in the case where only one or two slides are required) it is the most expeditious method of proceeding. If the negatives are large, the only way is to copy them in the camera; if the original negative is of moderate intensity, ordinary daylight diffused by a piece of ground glass answers every purpose. Should the negative be very intense, nothing but strong sunlight diffused by ground glass is of any use whatever.

(To be continued.)

SNOW SCENES.

MR. F. L. MORRILL, a correspondent of our excellent St. Louis contemporary, describes his experience in producing snow effects in portraiture. He says:—

"In the first place, the snow on the ground we make of 'coarse-fine' salt, bought by the bag of (say) 150 pounds, and spread upon an old background removed from its frame, and laid upon the carpet. It being painted, the salt will not sift through, and when you have done with it, take the ground by the edges and roll the salt to the middle, and with the help of your assistant lift it into a box for that purpose, made with a handle on each side, and carry into the accessory room out of the way, all of which is done in a minute's time, and the room is clear for sitting.

"In the next place, the snow on the coat, cap, accessories, &c., is the 'snow' sold by Mr. Seavey, the celebrated background painter, and is nothing more or less than the minute round bits of paper resulting from the manufacture of perforated paper. It is light, and by holding a handful above your subject, and sifting upon him, it will catch in the wrinkles of drapery, and very much resemble the genuine article. It has the advantage of being very clean, and can be very quickly brushed off, and for the drapery of ladies' dress nothing can be better.

"The falling snow we produce with a tooth-brush and India ink. Rub up a little in a 'slaut,' and laying your negative upon a bench in such a way that when you hold your brush over it, and lightly rub across it a bit of wire the spatters will fly on the plate obliquely, which will give a direction to the storm, and also elongate the flakes a little; and, by the way, the negative must be top towards you, in order that the flakes will be made to appear as if falling instead of ascending. Of course a few trials on a piece of white paper first will show you in just what direction to make the flakes fly, and also how thick the ink must be, in order not to have it run on the plate, and not have it fly in a mass, but in minute spots. The finer ones will represent the falling snow at some distance, and the larger ones nearer."

THE PLEASURES OF PHOTOGRAPHY.

[An American comic journal, the *New York Puck*, has the following scene in a photographic studio.]

He came into the studio with his wife on his arm, expectorated, and informed the artist that he wished to be "taken." "Naathin' fancy," he exclaimed, "jess somethin' plain an' quiet, to show the folks at home. I allow you kin get our measure, eh?" The artist thought he could. "How long 'll it take?" he inquired. "Reckon an hour 'll fetch it, eh?" He was informed that ten minutes' exposure would be amply sufficient. He looked grave. "I didn't calculate," he said, "on no particular exposure. There aint naathin' off-coloured about this business, is there? Ye see, I've been once to the theayter sense I come here, an' don't wish to risk my hold on grace by no unnecessary indulgence in vanities. This is a city of sin, ye know; an' I ain't going to let Satan get the pull on Isr'el Pettenhooper. I'm a deacon in the Smithfield Corners Brick Church, 'n I guess I know on which side the bread of salvation's buttered." Mr. Pettenhooper was informed that it was not he but the plate that required exposure; at which Mrs. Pettenhooper expressed herself much relieved. Then Mrs. P. proceeded to disembarass herself of her bonnet, which she did with some reluctance. The bonnet had evidently been in Mrs. Pettenhooper's family a long time, and probably dated from somewhere about the era of the French Revolution; for Pettenhooper's umbrella, an obvious octogenarian, was apparently some years the bonnet's junior. While this operation was going on, Mr. Pettenhooper drew the artist aside, and unbosomed himself in a corner. "I want you to understand," he began, "jess what

my idee is. My wife 'n' me, we don't want naathin' fancy, ez I said. We're plain people, 'n' jess about as godly ez they run at Smithfield Corners. So you see we want to git somethin' subdooel an' kind'r appropriat. We don't want no such things ez them I see downstairs—they in tights an' spangles, 'n' other unholliness. Mebbe," he went on meditatively, "mebbe I might want to come back, alone by myself, pussonally, for somethin' in that line. I presume you wouldn't tax me too high if I was to take a shine to a picture in tights? I s'pose it's the fashionable keerd?" Then, after reflecting a moment, and probably trying to raise the picture before his mind's eye, he added, with much animation—"Don't ye say naathin' to the old woman, though. She ain't got no sympathy with worldly idees. But gald ding it, I say, a man's got to hev his fling some time ruther, ain't he?" By this time Mrs. Pettenhooper was ready for the camera, and active operations were commenced. Considerable difficulty attended the artist's efforts to "brace up his sitter with the iron frame peculiar to photographers and the Spanish Inquisition. Mrs. Pettenhooper resented the intrusion of an iron thumb in the small of her back, and stigmatised the instrument as "immodest." However, ten minutes of artistic agony produced a ferrotypic of the deaconess. Then the trouble began. The artist came out of the darkroom, smiling and cheerful, with the plate in his hand. He showed it to Mrs. Pettenhooper. She asked in chilling tones—"Who is it?" This was a wet-blanket on the artist's professional enthusiasm. But he had no cause to complain of frigid moisture, for he found himself in hot water inside of two minutes. "Do you mean to say," was the indignant query of Mrs. Pettenhooper, "that I look like that? That thing? Why, 'tain't no more like me than 'tis like you. I don't believe you've took me at all. I believe, as I'm a Christeh'u woman, that you've taken some of them bareface'd creatures I see down in the showcase at the door instead of me. That me? An' you call yourself a photographer. I don't see how you've got the cheek to look me in the face, after libelin' it like that!" "I don't see but what it kinder fetches you, Mari," interposed Mr. Pettenhooper. "You don't? Pettenhooper, do you mean to tell me that that thing resembles the gal you used to sit on the fence with and make love to?" "Waal," responded her spouse reflectively, "come to think on it, I don't b'lieve it does. But," he added, in a confidential aside to the photographer, "No sir, that ain't the sort of thing I used to sit on the fence with, you bet. But the ole woman ain't held on to her youth like—like I hev." "I might touch it up to make it more like you," suggested the bulldozed artist. "You might!" was the reply he got from his sitter. And he did. He took it into the dark-room and touched it up. The result was a shade more satisfactory; but still Mrs. Pettenhooper refused to recognise her lineaments. She admitted, however, that it looked something like her grandmother; and the artist, somewhat encouraged, went away and touched it up again. The fourth touching-up proved satisfactory to Mrs. Pettenhooper, and she acknowledged that he had "somehow kinder caught the likeness," and added that photography was a wonderful art. Pettenhooper took his turn next, and when he got his ferrotypic he wanted to fight. "What do you call that blame machine?" he yelled. "That's a camera," said the trembling artist. "Camera, is it? Well, that there camera is a hurnin' infidel, iniquitous, unreliable, one-horse slauderer. What do you call a thing like that?" he thundered, turning to his wife. Mrs. Pettenhooper beamed with delight. "Why, if 'tain't's like you ez one pea is to another. Pettenhooper, I'd know you anywheres from this." "Oh, you would, would ye! Mrs. Pettenhooper, if you ever go to identifyin' me with that picture, I'll let a divorce court loose on ye. I'll go on a square old Talmage tear; I will, by gum!" "Perhaps I'd better touch it up," suggested the photographer. "No, sir, I don't want no touchin' up. Give me my umbrella and lemme go away from this deu of sin and iniquity." But he was told that ferrotypes always looked

that way at first, owing to the iron in their composition, and he finally consented to wait. It took six touchings up to bring Pettenhooper's portrait up to his ideal of manly beauty; but he was finally satisfied, though Mrs. Pettenhooper remarked that he was awful vain for a man of his age and a deacon in the church, and that the last picture was a piece of brazen flattery. Pettenhooper did not view it in that light, and he left the studio with a smile on his face, and the ferretypes in his pocket. And as he passed out he whispered in the artist's ear:—"Mebbe I will come back, some mornin' when the ole woman's out shoppin', an' try a picter with tights and spangles. A man's got to hev some swing, ef he is a deacon in the church."

Notes and Queries.

SPILLING HYPOSULPHITE OF SODA.

Your correspondent "Q. H." in "Notes and Queries" column, February 28th, should have the floor of his cellar thoroughly cleaned with water; after which, it will be easy to treat it chemically by pouring thereon a mixture composed of—

Muriatic acid	1 part
Water	3 parts

The soda hyposulphite will then be converted into sulphur, sulphurous acid, and common salt, which may be easily swilled off.

As asphalt floors vary somewhat in their composition, it will be as well to operate on a part of it, to see whether the sulphur precipitated adheres to the asphalt in a way that might be considered objectionable.

PHOTO-CHEMISTS.

DEAR SIR,—In answer to your correspondent respecting the hypo. disaster. The best remedy to overcome the consequences of going further is to well wash the floor of operating room, and asphalt over with a pint of glacial acetic acid in a pail of water—three times; when this is done, well wash again with plain water twelve times. You will find the substance of hypo. will all be out.—Yours respectfully,

W. J. ANCKORN.

62, Westminster Road, S.E., Feb. 28th.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on the 27th ult., at the Free Library, William Brown Street, Mr. THOMAS CLARKE in the chair.

The minutes of the previous meeting were read and confirmed.

The Secretary reported that the Associated Soirees had been a great success, and that another would probably be held at the close of the present year.

Messrs. H. Maycock and William Gorst were elected members.

The Secretary read a communication from Mr. H. Houlgrave, on "Some Experiments with the Gelatine Process" (in our next). In illustration of this paper a dozen stereoscopic transparencies were handed round, and were much admired for their softness and excellence. It was stated that these had been produced with about half an-ounce of emulsion, costing not quite threepence.

Mr. H. A. WHARMBY exhibited some charming portraits from gelatine dry-plate negatives. These had been produced in from two to five seconds in the studio, under conditions which with a bath plate would have been impossible.

The Rev. H. J. PALMER said he was glad to see gelatine dry plates were now being taken advantage of by the profession. He had that afternoon had a visit from a friend who was just going to New Zealand. He was desirous of taking his portrait, and though it was 4:30 p.m. he was successful with a London gelatine plate.

Mr. J. H. F. ELLERBECK exhibited some beautiful lantern slides of what are known as "pendulum curves." These were produced by the needle working on glass prepared by first rubbing over with wax (nearly polishing it off again) and then holding it over the flame of a piece of burning camphor—or, as Mr. Chadwick suggests in his "Magic Lantern Manual," turpentine will answer the same purpose. A perfectly opaque surface is the result, and the lines made by the needle are beautifully fine.

The members were reminded that the portrait album was not

yet full, and it was suggested that each member should be obliged to present his portrait for the album.

The meeting was then adjourned till the 27th inst.

PHOTOGRAPHIC SOCIETY OF FRANCE.

THE first meeting of the new year was held on the 10th January last. M. DAVANNE President of the Executive Council, in the chair.

After balloting for the admission of members proposed at the previous meeting, and the nomination of new ones, a letter was read from M. Henri Carliez, engraver, of Deville, near Rouen, describing a possible method of transferring to any required distance an image obtained in the camera, with all the gradation of tones and half-tints, by means of an instrument similar to that used for the transmission of sound. From an ordinary photographic negative a carbon positive or a print in gelatine can be taken, which will give an image in relief. By interposing between the carbon paper and the negative a stippled plate—a plate that is covered with dots placed at regular intervals, but more or less dispersed according to the character of detail in the image—and exposing to the light for some time, an image would be obtained formed of points or dots more or less deep, according to the intensity of the parts of the negative through which the light had passed. The author's suggestion is, that by a simple mechanism a pin may be made to pass over these points, and by means of a membrane to repeat their gradation in the same way as Edison's phonograph repeats the indentations which the sound vibrations have imprinted on the sheet of tinfoil. For receiving the image the machinery employed would be exactly similar, and the vibrations of the pin could be transmitted to a distance by means of Bell's telephone.

After M. PECTOR (who officiated as Secretary in place of M. Perrot de Chaumeux) had read a number of extracts from the foreign and home journals, the President submitted to the Society a Directory published by the Photographie Society of Vienna. This Directory—as yet complete only as far as the letter M—contains the names of all the photographers of the world arranged under towns, and the towns in alphabetical order. Any person consulting the work is requested to point out the errors and omissions he may happen to discover. It is much to be desired that the example set in this respect by the Vienna Society may be followed by the photographic societies of other countries. The arrangement of such a list, whose importance can scarcely be overrated, would then be much facilitated.

M. ROUSSELOU, Chairman of the Committee of Arrangement of the Photographic Section of the late International Exhibition, informed the members of the Society who had exhibited there that the Committee, having closed the accounts, were in the pleasant position of being able to return twenty-five per cent. of the amount paid in advance by each exhibitor. So soon as the accounts were completely made up, a full balance sheet of the receipts and expenditure would be issued.

A communication on the use of collodion coloured with the tincture of orcanet or alkanet for retouching negatives was made by M. LAMY, and an experimental demonstration of the process given before the Society. Full details of the process and of the preparation of this stained collodion will be found in our French Correspondence, at page 31 of our issue of the 17th January last. M. Lamy claims for this method the advantage that it affords an easy means of improving negatives which are either too weak or too intense. With good portrait negatives treated in this way he asserts that the effects of light and shade on the face may be increased or diminished, and the details of light-coloured clothes and of the hair rendered more distinct. In the case of negatives of landscape photographs, the different planes of the picture can be separated, and the effects of excessive high lights can be softened.

M. STEBBING suggested a theory for the cause of the spots which so often are found on plates prepared with collodion-bromide emulsion. These spots or striæ are in the form of horizontal lines, fine at first, but widening as they proceed, and ending in the broad flat curves like glass drops. They are due, according to M. Stebbing, to the moisture of the atmosphere and he therefore recommends that emulsion plates should always be prepared in a perfectly dry place.

A report of the Committee of the Society appointed to investigate the different emulsion processes on the gelatine-bromide plates of M. Garcin, of Lyons, was read by M. Ferrier. He exhibited some positive prints obtained by contact, and a negative taken in the camera, which showed that these plates were able to give very good results. As to their sensitiveness compared with that of other processes, the committee could express no decided

opinion, in consequence of the bad light with which they were obliged to carry out their experiments.

M. CH. CROS showed an instrument of his invention, which he names a chromometer. It consists essentially of a box blackened inside, in which are placed three glass plates parallel to one another, at an angle of 45° with the front of the box. Facing these are three openings furnished with slits for holding glass troughs containing standard coloured solutions. These are a red solution of cobalt chloride, to which some potassium sulphocyanide is added; a yellow one of neutral potassium chromate; a blue one of copper nitrate. When a double trough of each of these coloured solutions is placed before each of the three openings, and all are equally illuminated, the effect produced by the combination of the three reflections on looking downwards on the glass plate is that of white light. If the red aperture be masked by an opaque screen, there are only two reflections combined, the blue and the yellow, and the effect produced is that of a less brilliant white. If the yellow aperture be masked, the tint produced is still white, but tinged with violet; and if the blue aperture be masked, it will be tinged with orange. Next, instead of using double troughs of the same coloured solution, let them be employed in pairs—that is to say, in one aperture a trough of the yellow, and another of the blue solution; in the second, the blue and the red; and in the third, the red and the yellow, so that only green, violet, and orange light are respectively transmitted. The effect when all the apertures are open will be, as before, that of white light, but when the opaque screens are used the appearances are completely altered. When the green light is stopped, the colour of the ground is a pure carmine; with the violet suppressed, a pure yellow is seen; and when the screen is placed before the orange aperture, a pure blue is produced; all these pure colours being the same as those seen in the trichromatic spectrum when a black bar on a white ground is viewed through a prism. M. Cros has also applied his chromometer to the examination of photographs taken by light transmitted through coloured media. Thin negatives reproduced from the same coloured picture are taken through a green, a second through a violet, and a third through an orange medium—the media being obtained by combining, as above, two and two, the three standard solutions in flat glass troughs. Black positives were then taken from these negatives, and placed one in each opening of the instrument, and a combination of troughs of the same kind as that which served to stain the light for each negative respectively placed in front of it. When the reflections from the three glass plates were viewed in combination, and the light properly regulated, the effect produced was exactly that of the coloured picture from which the three negatives were taken.

PHOTOGRAPHIC SOCIETY OF BERLIN.

At the meeting of the 2nd January last, Herr H. JOOP read a paper on "Some Innovations in the Carbon Process." He commenced by observing that the word *innovations* had not been chosen by him, and hardly expressed the intention of his communication, for although some of the manipulations he desired to bring before the notice of the meeting had never yet been published, they were not exactly quite novel. Pigment or carbon paper, he remarked, could be purchased comparatively cheap and of good quality. Care should be taken that the negative employed be of sufficient intensity, for a carbon positive copies rather softer than one on albumen; also that the chromate bath be of the proper strength. A strong solution of chromate (five per cent. and upwards) gives a weak picture, while a dilute one of about two per cent. has the contrary effect. By correctly estimating the bath, therefore, serviceable prints can be obtained from a hard or weak negative. Attention should also be paid to the desiccation, as a paper that has been dried rapidly gives a harder picture than one dried slowly; though the latter is more sensitive, protracted desiccation would increase the sensitiveness by about two-thirds. For transferring the film to the glass plate the author had tried the plan of Herr DUBY, the principal feature of which consisted in immersing the paper, after exposure, in a weak solution of shellac in alcohol, but had found that the water retained by the paper soon rendered the shellac solution milky, and spoiled it. He preferred coating the glass plate with a varnish of—

Oil of turpentine	4 parts
Gum dammar	1 part

which was allowed to dry for twelve hours. Water was then poured on this plate, and the carbon paper, after having been dipped for a short time in cold water, placed film downwards upon it, and thoroughly squeezed in every direction. By this

method the formation of bubbles is avoided. Another defect, that of reticulation, which often occurs in the parts where shadows and lights are sharply divided, is due, in the opinion of the author, to the gelatine film tearing on its upper surface, in consequence of those portions that have been less acted on by light swelling up more quickly than the others. This may be corrected by performing the first operation of washing as quickly as possible, so as to allow the gelatine no time to swell up. In developing, only moderately warm water must first be used, and hotter water only after the paper has been completely immersed in the bath. For developing carbon prints Herr JOOP uses an apparatus of his own devising; this consists of a rectangular trough 86 c.m. by 70 c.m., with deal sides 15 c.m. deep, and a double bottom, the lower one of iron, the upper one of zinc plate. It is heated by an atmospheric gas stove, oval in shape, placed underneath the iron plate. As regards the different kinds of paper that he uses for obtaining carbon negatives, he observed that the English paper No. 107 gave the best results; it possessed a steel-grey tint, and gave more intense copies than the red-brown paper A5 of Braun. In the discussion which ensued,

Herr E. DUBY expressed the opinion that copying in direct sunlight after a weak chromate bath was not reliable, as it was difficult to attain the desired intensity. Slow desiccation, he believed, would certainly heighten the sensitiveness, but had the disadvantage of rendering the paper less durable. As regards the shellac process, which he had introduced, he thought the author of the paper must be labouring under an error, as he had always recommended a thorough squeezing of the paper on to the glass before immersing it in the shellac solution, so that it retained but very little water, and the shellac solution would remain good a long while. In conclusion, Herr DUBY drew attention to a very sensitive paper manufactured by Dr. Van Monckhoven, which was sold under the name of "Papier special pour climats chauds et pour agrandissements."

Herr CARL SUCK had found that the English carbon paper 107 could not be used for negatives, as it soon fades and turns of a greenish-grey colour.

Herr DUBY believed that this greenish tint was due to progressive decomposition of the chromic salt in consequence of insufficient washing.

Herr H. JOOP considered a paper tinted with cochineal to be quite useless for transparent pictures. For retouching he had used a mixture of burnt carmine, burnt sienna, a little neutral colour, and some lampblack, which he thought could be employed with advantage as a pigment for gelatine films.

At the meeting of the January 16, Herr C. BRASCH in the chair, Dr. F. STOLZE read a paper on his "Photographic Experiences in Persia." After an exhaustive account of the country, its geographical and climatic relations, and a short sketch of the work of the expedition for the observation of the transit of Venus, he entered fully into the difficulties he had met with as a photographer in the course of his journey. With more than three hundred emulsion plates he obtained very poor results, as the orange yellow glass of his transfer box proved to be no protection against the intensity of a Persian sun. Dry plates also, whether prepared with coffee, tea, or beer, proved also unsatisfactory, so that he had to fall back on the wet process. For this purpose he used a box which served the double purpose of a receptacle for chemicals, but its limited dimensions, the want of water and a dark tent, and the insupportable heat, compelled him to cut short his stay in it. On this account the plates, immediately after being developed, were coated with a concentrated solution of sugar, and the washing and fixing put off till later. In obtaining the necessary chemicals, he met with incredible difficulties—for example, a collodion procured from Bombay proved to be a model of worthlessness. According to the opinion of the speaker, English dealers send out to India only those articles that cannot elsewhere be got rid of. Either it was quite impossible to procure, for the bottles on their arrival, notwithstanding the most careful packing, were sure to be nine-tenths empty; but as Dr. Stolze on one occasion had sent to him sulphuric acid in place of the sulphuric ether which he had ordered, he was able, by means of an ingenious arrangement, and with the help of the arrack of the country, to make for himself the required substance. After much trouble he procured, by the agency of a compatriot, some lunar caustic and raw collodion, from which he was able to prepare good collodion emulsion, and thus to obtain some most successful views of the ruins of Persepolis. Dr. Stolze increased the interest of his paper by the exhibition of a number of prints from negatives taken in Persia.

Herr E. DUBY showed a number of carbon negatives taken on paper of various kinds, and corroborated the views of Herr H. Joop, expressed at the former meeting, as to the superior fitness of the English paper 107 for taking carbon negatives.

Herr C. BRASCU laid before the meeting a number of euaesthetic photographs, which were highly approved. He stated that this kind of photograph for the decoration of table porcelain is beginning to obtain a wide distribution.

Herr Th. JOOP introduced to the notice of the Society a new pneumatic holder of iron for plates of a large size—more than a square metre in area. The ingenuity of the construction of this instrument was universally recognized, but doubts were expressed whether its price (50 marks) would not prevent its general adoption. Herr H. JOOP has also constructed a plate-holder, much cheaper in price, which he promised to exhibit at the next meeting of the Society.

Talk in the Studio

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday next, March 11th, at the Gallery, 5, Pall Mall East, when Mr. C. Beuett will read a paper on "Gelatine Emulsion." Mr. W. Wainwright, Jun. (Woking) will exhibit gelatine plates, with some remarks; and Col. Wortley will exhibit samples of pyroxyline washed in ammonia.

THE LUXOGRAPH.—A letter from Messrs. Alder and Clarke, whilst thanking us for our article of last week, takes occasion to state that the pyrotechnic compound they use is not the same as that which was employed by Mr. Moule, but one of their own, giving a more intense light, and consequent shorter exposure; the time for a cabinet head with Dallmeyer's No. 2 B, second size stop, being from 13 to 15 seconds. They take exception to the term "huge" as applied to their reflector, which is 4 feet 3 inches in diameter.

ALLEGED PIRACY OF WORKS OF ART.—At Brighton a photographer, named John Patrick Conroy, was brought up on a warrant charging him with having infringed the copyright of certain works of art, the property of Mr. Henry Graves, the well-known fine art publisher of Pall Mall, London. The first charge was of infringing the copyright of Frith's celebrated picture of "The Railway Station," which, with the steel-plate engraving, &c., was purchased by Mr. Graves at a cost of £16,000. So long as ten years ago a photographer, named Singleton, was employed by a tradesman, named Greig, in Guernsey, to produce a negative from an engraving of the painting, which negative subsequently passed into the prisoner's hands by purchase, and three photographs, measuring about 12 in. by 8 in., were shown in Court as having been taken from it. It was explained to the Bench that prisoner was liable to a penalty of £10 for every pirated copy, but it was preferred to take the case under the Small Penalties Act, so that prisoner might be made liable to be committed to prison. Prisoner's reply to the charge was that the photographs were produced in Guernsey, to which island the Copyright Act did not extend; and eventually a remand was granted, it being understood that the other charges, including the pirating of the "Pair of Nutcrackers," "The Good Shepherd," "On Foreign Service," and other well-known pictures, would ultimately be gone into.

THE LATE MRS. CAMERON.—The *Times*, referring to the special loss to a social circle by the lamented death of this lady, says:—"Mrs. Cameron appealed to a still wider public by her perfectly original and unique photographic work and subject pictures, in which, after a daring fashion of her own, forfeiting the sharpness of definition which ordinary photographers strive for, and which is one of the things artists most dislike in photographic portraiture, and having the advantage of sitters usually distinguished for intellectual gifts or personal graces, she produced a series of heads and groups quite unique in their suggestiveness, the most picture-like photographs certainly which have been given to the world, and some of them among the best extant portraits of their distinguished originals, which included, among a host of other notables, the Poet Laureate, Sir Henry Taylor, Sir John Herschel, Herr Joachim, Mr. Spedding, and the Rev. Mr. Brookfield. Mrs. Cameron's singular ardour of enthusiasm, the energy with which she flung herself into whatever she undertook, her rare forgetfulness of self and readiness to help others, endeared her to a wide circle of friends, while her devotion to her family was for her a love which nothing ever diminished—not even her departure for a distant island, whither her affection for her children carried her at a time of life when the

long journey and the difficulties and discomforts of forming a new home would to most women have been insurmountable. Brought back to this country last year by the impaired health of her venerable and distinguished husband, who survives her, she bore the journey with her usual hardihood and spirit, and her friends were delighted to find all her old force and freshness of character and temperament undiminished."

To Correspondents.

NORTHUMBERLAND.—The chief object of immersing the gelatine in methylated spirit is to remove all the water. Absolute alcohol will of course answer, but the same spirit will not serve for repeated use. It may be re-distilled to get rid of the water it absorbs. 2. In distilling water, a lead pipe may be used for conveying water to the still. The caution you have seen is against the use of a lead pipe for the worm of the still. This should be of copper or brass.

M. H. W.—The spots are, we think, due to imperfect fixation, but produced in a way often little suspected. It is caused by the formation of small air-bells on the print, which protect the spot from the perfect action of the hypo. The circular nature of the spots indicates this as a source. The stains caused by imperfect fixation are never visible until some hours afterwards, when light and moisture have caused the decomposition of the insoluble hyposulphite of silver formed. The cold weather would conduce to this result. Warning the fixing solution is very desirable in cold weather. Hyposulphite is not likely to deteriorate whilst kept in crystals.

NELLIE.—The yellow circular stains in your prints are precisely similar to those of "M. H. W." Read the answer given to him above. Watch the prints when placed in the fixing bath, and remove air-bells which form on their surface. It is a good thing to keep the prints moving in the fixing bath, lifting each individual print, and placing it again in the bath. This removes air-bells, and prevents the prints sticking together, which is a frequent cause of imperfect fixation. We shall always have pleasure in giving NELLIE advice, so she need not hesitate to ask.

B. HEYNE.—The power of reducing the intensity of parts of the negative would, of course, be useful, if it could be easily and safely done. But you write as if you had already communicated to us your method. There is a mistake somewhere, as we have not had any letter from you before this in which you ask if it would be wise to advertise your method.

TONED COLLODION TRANSFERS.—Your letter raises a question which has often occurred to our own mind, but has never been discussed, nor, so far as we know, any evil results been noted. When toning a collodion transparency, the chlorine liberated from the deposited gold will, undoubtedly, form chloride of silver by combining with the silver forming the image. But all this, you must remember, is in the dark parts of the picture, and if this chloride blackened under the action of light, it would only intensify the image. You speak of the light's becoming discoloured. As the whites are simply clear collodion, containing no silver, they cannot darken from this cause. If they darken at all, it is from some other cause. Some samples of spongy collodion require much washing to clear them of anything in which they have been immersed, and possibly traces of the gold solution, or even of the previous hypo solution, remain, and subsequently cause discoloration. If traces of the fixing solution remain in the film, the whites will sometimes discolour during toning. Prints which have a good colour after developing, without toning, often have a buried smoky looking image. Varnishing will remove this.

R. G. D.—Gelatine which dissolves in cold water is bad, and should not be used for photographic purposes. A special test of gelatine or glue is that it should swell in cold water, but not dissolve without heat.

J. R. H. will find several articles giving instructions for producing rapid dry plates in our last and preceding volumes, also in our YEAR-BOOKS. We cannot repeat complete processes in this column, nor, indeed, in any column, when they already exist for ready reference. Justice to regular readers forbids such a plan of occupying our space. There are several articles on the subject in our YEAR-BOOK just issued. See page 38, where Mr. Henry Cooper gives very full instructions for an excellent process.

A. K. H.—You will find, we think, that diluting your collodion with a little of a thin undiluted sample will remove the difficulty.

PARIS.—The gentleman to whom you refer has not specifically given up photography; but some short time ago a very severe domestic grief caused him to withdraw himself considerably from professional life. We do not feel at liberty to publish an address which might, by any possibility, submit him to intrusion. Our correspondent will readily understand this. Under other circumstances, he was courteously accessible.

Several correspondents in our next.

The Photographic News, March 14, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.
TRAVELLERS AND DRY-PLATE PHOTOGRAPHY—THE DIRECTORY OF THE PHOTOGRAPHIC SOCIETY OF VIENNA—JOURNALS ILLUSTRATED BY PHOTOGRAPHY.

Travellers and Dry Plate Photography.—It would be well, indeed, if travellers could derive more benefit from the improvements that are taking place in dry plate photography. It is no longer a novelty to employ dry plates in the studio in preference to wet ones. Several of our correspondents have now been employing gelatine emulsion plates in the studio for months past, and the silver bath, if not put on one side altogether, has not been called into requisition. But in the studio there is a dark room always at hand, a haven of safety and refuge to the photographer, which the traveller, unfortunately, lacks. If things do not go quite as they should do, the stay-at-home photographer has always his dark room to go into, wherein to investigate the circumstances of his failure. He can always see how far he has succeeded or failed on the instant, and may at once investigate the cause of failure. His sifter is still in the next room, and another plate can be taken without loss of time. The traveller, unfortunately, is in a far worse position. If he does not burden himself with a dark tent, then he must run the risk of failure with his dry plates; if he carries a dark tent with him, the advantages of dry plate work cease to have their full importance with him. There is no doubt, too, that a photographer who is not well versed in dry plate development gets nervous over the manipulations when he knows that the object he has photographed is, perhaps, left far behind in his journey, and there are no means of retaking it should his plate turn out a failure. He is not working under favourable circumstances, and he gets more failures than would otherwise be the case. Under the circumstances a traveller never seems to feel confidence unless he carries materials for the wet process, and, when he has these with him, he naturally employs them. The experiences recently detailed by Dr. Stolze before the Berlin Photographic Society are not likely to give travellers any further confidence in dry plate work. Dr. Stolze has made a journey through Persia, and his results, obtained not with a few, but a large series of dry plates, must have been very discouraging. He tried during his wanderings, he tells us, no less than three hundred emulsion plates, with which he obtained very poor results, owing, he explains, to the yellow glass of his transfer box not being proof against a Persian sun. If the emulsion plates had been prepared with gelatine, we can well believe the traveller's explanation, and it certainly behoves travellers to bear in mind that protection which may be sufficient in a European climate, fails to preserve plates from immunity in the East; but Dr. Stolze's other dry plates were not more satisfactory. Films, whether prepared with coffee, tea, or beer, were not to be relied upon, and, in the end, Dr. Stolze had to do what many before him have done, namely, get along as well as he could with the wet process. This resolution did not at once remove all thorns from his path. The want of water and a dark tent, together with the insupportable heat, compelled him in the end to cut short his photographic tour in Persian territory. He did not wash and fix his plates, but contented himself with developing them and coating them with a solution of sugar. Dr. Stolze's woes as a travelling photographer appeared to be never-ending. He had believed so sincerely in his dry plates that he had come almost unprepared to work by the wet method. He complains that at Bombay no collodion of any worth was to be obtained, and he hints that dealers appear to be in the habit of sending out such photographic material to India as they cannot get rid of elsewhere. Either it was impossible to procure, since the bottles arrived always nine-tenths empty. We suspect the circumstance goes a

good way to explain the dearth and inferiority of other articles—such as collodion, alcohol, &c. Ninety degrees in the shade must play a good deal of havoc with photographic chemicals, although we have many correspondents in India who have never complained against difficulties from this source. Dr. Stolze would have us believe that at last he was so reduced in the matter of supplies that only lunar caustic and raw collodion remained to him, with which he prepared some emulsion that secured very good views of the ruins of Persepolis. No doubt climatic influence must work an impression upon dry films, and an emulsion or coffee plate prepared in England or Germany no doubt would hardly give such successful results after the vicissitudes of travel in an Eastern country; at the same time, we remember, Captain Abney had little difficulty at Thebes with films prepared in England prior to his departure. The plates in the latter case, it is true, were prepared by himself, and, as Captain Abney is *facile princeps* in all that pertains to dry work, no doubt the films were handled with unusual skill; but still there is the fact that they were not found wanting. Captain Waterhouse, the Assistant Surveyor-General at Calcutta, has also worked repeatedly with dry plates, and has secured eminently satisfactory results. In the case of both these officers, of course, they are well acquainted with the Tropics, and it would be well if they could be prevailed upon to place on record their experiences on the preparation of dry plates to be employed in hot climates.

The Directory of the Photographic Society of Vienna.—The Photographic Society of Vienna is in the van in many respects. They have for years past issued a series of medals for progress and improvements in various branches of the art, and they organize lectures from time to time for the good of members and their friends. Under the Society's auspices, the President, Dr. Hornig, has regularly issued, of late years, an annual or note-book, for the use of members and photographers generally, which contains a mass of useful information. There are the names of all photographic societies in the world, together with their chief officers. All the known photographic journals published in Europe, India, and America, are given, with their place of publication; a list of photographic requisites which are poisonous, and what the antidotes are for such poisons, together with a mass of other useful information. Now the Vienna Society has published the first part of a General Directory. So far it is only complete as far as the letter M, and it is to contain the names of all the photographers in the world arranged under towns, and the towns in alphabetical order. The Society depends upon home and foreign photographers to point out errors, if they exist, and these will be corrected in a second edition of the work.

Journals Illustrated by Photography.—Photography is being utilized again in the illustrated papers for depicting war sketches. One of the finest plates in the *Illustrated London News* of last week is from a photograph by a Durban artist. It shows the crossing of Col. Pearson's column, a flat-bottomed barge filled with Linesmen going on duty across the river, while in contrast with the neat, soldierly uniforms are shown two or three Kaffirs in war paint and feathers. The scene is a most realistic one, and has all the life and reality which attach to a camera picture. We cannot see why a journal containing nothing but photographs should not be issued illustrated (say) both by the Woodburytype and the Collotype process. There should be hardly less delay, upon receipt of negatives, than is required to transfer a sketch on wood, cut the blocks, and have them prepared for printing. By having half-a-dozen photo-mechanical printing surfaces prepared, the delay that might occur from pulling off slowly would be at once neutralised. The sale of such a journal giving (say once a week) four or six prints of interest would command a ready sale, and as people now pay sixpence apiece for a great many of the London journals, double

that sum at least would soon be forthcoming from real photographs depicting scenes in Zulu-land, Afghanistan, or any other place to which popular interest attaches.

ARTIFICIAL LIGHTING.

BY R. P. HARMAN.*

IN introducing the subject of artificial lighting (and this paper in itself is but an introduction), I feel that some apology is due from me to the members of the Society; for during the past few weeks it has apparently become such an all-absorbing topic, and the newspapers, as well as our own orthodox photographic journals, have so taken up the matter, and related all the hitherto known or published facts and fallacies concerning it, that it needs a far more powerful exponent than myself to do it justice. I will, therefore, not waste your time by making this paper a resumé of what must be already known to most of my hearers, but will briefly give you my own experience, trusting in a subsequent discussion to elucidate some new facts, and make the subject an interesting one.

A question arises at the outset, Is it advisable to investigate and persevere in the application of artificial light for photographic purposes? A professional photographer so strongly condemns it in a letter to the PHOTOGRAPHIC NEWS of the 21st ult., calling it a "night business" and an "ignis fatuus," with many other unwholesome remarks, that I confess I have been somewhat anxious lest my paper should meet with an unfavourable reception. This gentleman says: "Photographers have enough to do," &c., &c. But I believe there are many photographers who have not had quite enough to do during the last four months, and who would gladly have made a little profitable overtime. I shall therefore address my remarks to "whomsoever it may concern," believing that it concerns not only photographers, but hundreds of thousands of would-be patrons in all classes of society, who are not at liberty until the day's work or the day's duties are over.

What is more common than for a city gentleman to rush into your studio about nine a.m., with watch in hand, and just ten minutes to catch the train, his face flushed with heat and anxiety lest the said train should go without him, and he wishes to be photographed? His wife has been worrying him for years for his portrait, and now he remembers that to-morrow is her birthday, and thinks he will order a portrait of himself on his way to town, and call for it in the evening, just by way of a surprise for her. Your feelings prompt you to let him catch his train comfortably—in fact, to decline the little job, or, at any rate, to request that he will defer it until he has a more leisurely opportunity; but you cannot afford to lose customers, and the chances are that he will be taken in some London skylight during his quarter of an hour's luncheon, and you lose him altogether. You therefore prepare a plate as quickly as possible (unless you are so fortunate as to have a dry plate quite handy), your visitor in the meanwhile pacing the studio impatiently, and calling out for you to be quick, or he must go. You may easily imagine the kind of expression and the kind of negative you are likely to obtain under these circumstances. Your sitter hurries away, and cannot stop to pay, even for the proof; the proof is not quite to his liking when he calls; and his promise of a re-sitting is never fulfilled.

This is one class of people, and their number is legion, who live in the suburbs of London, and who never can spare an hour to be photographed, and to this want of opportunity I attribute the large number of lady-sitters compared with gentlemen who visit photographic studios generally. There are, of course, exceptions to this rule, and it may not apply to London; but the experience of many photographic friends, as well as my own, gives the same teaching. Now, if the City gentleman that I have alluded to would wait until after business hours, and after

his evening meal, he would come in a far happier and more tranquil state of mind, in good humour, and just fit to be photographed. Instead of a trial, it would be a treat, like going to the theatre (especially when he saw the blue fire) or like taking a stroll by moonlight. The same argument applies to artisans and the working classes generally, who can only find time to dress respectably after working hours. To these I am sure it would be a "real convenience," and I think the few specimens I have brought with me this evening will prove that the subject is worth studying, that it is not quite an *ignis fatuus*, and that it is also within the means of the humblest photographer.

The apparatus that I use is simple in the extreme, and as I have not tried either the electric light, the photogen, or the luxograph, I will leave it to those who have done so to speak of their merits. I have no doubt they are all good, perhaps far superior to my own—they ought to be; but then they are not within the reach of all. The electric light, for instance, was quite beyond my purse; with regard to the other two methods I have mentioned, I have only seen one demonstrated, and that did not impress me favourably. I am accustomed to quick exposures, and when I saw a gentleman exposed to a blinding light for exactly thirty-five seconds, with the burning material hissing and crackling all the time, I tried to calculate what chance I should have with nervous sitters, and how many I should pass in an evening's work.

On account of the objectionable noise and smoke attending the combustion of pyrotechnic compounds, I resolved to try what could be done with magnesium ribbon. I took an old umbrella, and divesting it of its stick, I converted it into a reflector by lining it with white paper. I then procured a child's wooden hoop, which I covered with white tissue, and this I hung loosely over the open part of the umbrella. The latter was fixed edgewise upon a head-rest, and in this I burnt the magnesium ribbon. I found that four inches of wire gave me about ten seconds' exposure, which proved quite sufficient for one of Wratten's gelatine plates.

My first attempts with magnesium were so satisfactory that I believe, with perseverance, I should have produced some excellent portraiture; but a friend having given me a formula for a very cheap pyrotechnic compound, I was induced to give it a trial, and I have now finally adopted it. My mode of using it is as follows:—An empty box without a lid (of any dimension, but the larger the better) is stood upon end and raised about three feet from the floor; the open part, facing the sitter, is covered with white tissue except about six inches from the bottom, to allow for draught and to put in the fire powder; the inside is lined with white paper; a hole is cut in the top not less than six inches in diameter, and over this I invert a flower pot with the bottom knocked out; and a cardboard chimney taken through a window effectually carries off the fumes.

A more concise and possibly more lucid description of a similar construction is given by the Rev. H. J. Palmer in the PHOTOGRAPHIC NEWS of February 14th; it resembles my own with a few exceptions, one being the novel smoke-holder, or chimney, for drawing-room purposes. This I gave a fair trial, but found it impracticable, for unless it is made of an enormous size it will not hold the volume of smoke for ten seconds' combustion, and it is, of course, necessary to wait until "the last faint spark expires," before you can remove it. One ounce of the compound will burn for ten seconds, and as this is about the usual exposure (although good negatives can be taken with less), the cost of production will be one half-penny for the light. I use it in the following manner:—A sauceman lid is filled with dry sand, and laid on a trivet about six inches high in the centre of the box; the powder is then poured on the top of the sand in the shape of a pyramid, a hole is made in the side of the box about one inch in diameter, through which I can watch the fire and insert a wax taper to light it.

* Read before the South London Photographic Society.

I have here given the most economical way of working the process, although I am not insensible to the advantage that would be derived from having suitable reflectors (mine are all paper ones). The fire-box may be lined with tin to produce a more powerful light, and if made on purpose, the box would be better in the shape of an old-fashioned corner cupboard.

While on the subject of apparatus, it may not, perhaps, be altogether irrelevant to describe the lantern with which I develop dry plates. It is a box of precisely similar construction to the fire-box already described, with a cover to hang over the front, made of cardboard and deep orange coloured paper. In the box I place a good paraffin lamp, and I find it quite effectual, as I have held dry plates in front of it for two minutes without fogging. There is another hint which may be useful to those who use gelatine plates for the first time. It is very convenient to take a print from the negative before varnishing, so as to re-intensify if not sufficiently done; but unless great care is taken to have both the negative and paper thoroughly dry, the gelatine film will become impregnated with the silver from the paper, and will soon blacken in the daylight, becoming worse and worse with every print, until the negative becomes useless, unless the varnish (if it has been varnished) is removed, and it is again placed in the hypo bath. The negatives that I have brought with me this evening were all taken with dry plates with exposures varying from six to ten seconds. With regard to those negatives, and also the prints from them, I wish it to be understood that I have brought them only to show the effect of lighting and exposure; in other respects they are extremely bad, and must not be taken as a specimen of work. I shall, therefore, feel obliged if you will kindly return them to me after inspection. With one exception they are entirely untouched. I have purposely left them so, as we all know what can be done by elaborate retouching, and it is impossible to judge of the merits of a negative when it is piled up with so many permanent pigments of plumbago.

A NEW TONING PROCESS FOR LANTERN SLIDES AND TRANSPARENCIES.

BY WILLIAM BAOOKS.*

As regards the exposure. When the system of contact is used, expose from about one second to five or six, according to the intensity of the negative, in the front of an ordinary window (without opening it). In the camera the exposure is longer. With a good light, when using whole-plate negatives, from about twenty seconds and upwards; with a very intense negative, sometimes two, or even three, minutes will not be found too long; but, as a rule, give plenty of exposure, as an under-exposed plate is useless.

The year before last I read a paper before the South London Photographic Society, respecting the colour of the developed image, so as to obtain rich warm tones by using in conjunction with the alkaline pyro developer certain salts. I obtained the best results with acetate of soda, and also phosphate of soda. Very charming results were obtained by this means, but the system was only available when the warm tints were required; it was useless for black tones. Since I published the results of those experiments, I have investigated the matter still further. I find that different samples of pyrogallie acid will give different tones. I have now in my possession three different samples: one will develop the image of a warm red tone; another gives an image of a greenish tint with good intensity; and the third sample gives a very thin, slate-coloured, miserable looking thing, and no amount of alkali will alter their character. Then, again, I find also different results obtained by using different samples of carbonate of ammonia. I believe there are two sorts in the market—the ordinary commercial, and the re-sublimed. The former sample has the tendency to give a greenish tint to the image; and the latter generally gives a

rich vigorous tone, with a reddish cast. I always find it best, when purchasing, to get this article from some large wholesale house. Several times, when I have run short, I have obtained some from the nearest chemist and druggist—and to my sorrow. I find the best way of keeping carbonate of ammonia is to keep it in a jar or wide-mouth bottle, with a well-fitting cork, and keep the bottle or jar, *mouth downwards*, in the coolest place in the house. Liquor ammonia gives, generally, a bluish kind of image, and I very seldom use this at all.

After the plate has been exposed either by contact or in the camera, it is flooded with three parts of methylated spirit and one part water, allowed to soak well into the film for about one minute; the plate is then well washed (or, what is preferable, soaked) in a dish of clean water for two or three minutes, and then well washed under the tap, and a developer poured over, made from the following solutions:—

- A.—Saturated solution of carb. ammonia 4 ounces
- Bromide of potassium 2 drams
- Water 8 ounces
- P.—Pyrogallie acid (best) 96 grains
- Absolute alcohol (805°) 1 ounce

For a quarter-plate put about two drops of solution P into a clean measure, and about two drachms of solution A, and pour over the plate at once. I prefer to develop the small plates in a little cemented glass dish, as described by me some years ago in one of the *YEAR-BOOKS*, as I can easily see through it and watch how the intensity is going on. I find, as a rule, almost every sample of emulsion will stand the developer compounded as above. Should the subject be one of violent contrasts, one drop of pyro will be found sufficient, and with a weak and flat negative five or six drops will not be found too much. The image must be developed to its full intensity—if anything, a little above—as the fixing agent used is more powerful. After the plate has been well washed, it is fixed in a solution of cyanide of potassium. Hyposulphite of soda is useless in this instance. I use it about the following strength:—

- Cyanide of potassium 20 grains
- Water 1 ounce

It will be found best to use this in a dish, and immerse the plate in it, moving the dish about. It will fix in about two or three minutes. By using cyanide instead of hypo, we obtain one of the most wretched colours imaginable—of a nasty yellowish buff, and it is by obtaining this colour we are able to tone to any tint we please. Care must be taken not to allow the cyanide to act after the film is well cleared, especially if the image is thin; but, at the same time, all traces of the unaltered bromide of silver must be dissolved. The plate is now washed under the tap for about a minute, and then allowed to soak for about a quarter of an hour in a dish (the larger the better) of clean water. This washing must not be skirped, or the toning will be uneven. When removed from the dish of water, it is again well washed under the tap, and is then ready for toning.

The best toning agent I find for the purpose is bichloride of platinum. I have tried chloride of iridium, and though I have not yet succeeded to my satisfaction, have not given it up.

Toning Solution.

- Bichloride of platinum 2 to 4 grains
- Water 20 ounces

The toning is best accomplished in a white dish. After the plate has been well washed, it is placed in the toning bath, and the dish must be well rocked about to insure even action. It will at once change from the miserable yellow colour before described, first to an orange tint, and then to pale claret, to deep claret, to purple claret, pure photo-tone, warm black, deep black, engraving black, and finally to a slatey black, something like platinum gives with an ordinary bath plate. Now the toning can be stopped at any stage, according to taste and subject. It almost may be termed a magic system of toning. If the plate has not been washed sufficiently, it will tone in streaks and patches, which can never be over come unless the toning is carried on to the slatey

* Continued from p. 116.

tints. After the image has been toned sufficiently, it may, perhaps, be found a little too intense to give the best result on the screen; if so, it can be passed through the cyanide again. In so doing, if only the red warm tone has been obtained, the tone instantly is destroyed on immersion in the cyanide solution, which also at the same time reduces the image to the required depth; but if the black tones have been obtained in the first instance, it has but little effect upon the colour; the only effect the cyanide solution has, is to reduce the intensity or clear away fog. The warm tones are composed of silver and platinum, and the black tones of platinum only.

Now if we compare a slide that has been toned with one that has not been toned, it will be readily seen that the toned one is far superior as regards texture and clearness. The untoned slide looks almost perfect when seen alone, but together the detail has the appearance of being clogged up. The black cold tones are very suitable for making enlarged negatives.

I must not omit to state that it is impossible to get good tones on very weak images. Better tones are obtained in transparencies that are suitable for decorative purposes, but lantern slides can be made sufficiently intense to bear any tone required. I am in hopes, in a few years, to see a greater interest evinced in this beautiful branch of our art-science than it has hitherto received.

One drawback with the system that I originated with the use of acetate of soda, &c., with the alkaline pyro, was, that it was at times difficult to get a series of transparencies of the same tone; but with this method the toning can be stopped just at the moment the desired tone is obtained, exactly the same as a silver print.

Before I close, I must also call attention to the bichloride of platinum. Samples at times will vary, and I hope I shall not transgress the limits allowed to contributors in these pages in stating—mostly for the benefit of photographers residing at a distance from large towns or cities—that bichloride of platinum can be obtained at Messrs. Hopkins and Williams, Cross Street, Hatton Garden, as I am well aware that it is not kept in stock by the ordinary photographic dealers. I am also busily engaged in working out several other branches of photography where platinum toning plays an important part, and also hope to have the pleasure of making them public.

I must not omit to mention that the toning need not be done in the dark-room; it can be done in full daylight, as it has been fixed, by toning in a white porcelain dish; lifting the plate up at about the angle of 45°, the tone is readily seen. Should the solution tone too rapidly, it can be diluted with water. Use ordinary tap water. After washing and drying, it can be varnished in the ordinary way. The best varnish that I find for the purpose is made as follows:—

White hard spirit varnish ...	1 part
Methylated spirit ...	3 to 6 parts

according to the thickness of the white hard varnish. Some samples will bear more spirit for diluting than others. For lantern slides it is best to use the varnish as thin as possible; if used too thick, after a time it will crack, from the heat of the lantern. The best guide is to thin it down so that only a slight gloss is seen on the varnished film; if it is too thin, it dries dull and dead. I have seen many slides ruined by using the varnish too thick.

In conclusion, I will give a hint or two about mounting. I generally use masks black on both sides, and on one side I write the name of the subject in white. For this purpose I use moist tube water colour, and thin down to the consistency of cream, using an ordinary steel pen kept for the purpose, keeping the bottle containing it well corked when out of use. By adopting this system the white letters can readily be seen in a dull light, and the side that the inscription is written on goes next to the light, unless the pictures are being shown through the screen, when it is reversed. Mr. G. W. Wilson adopts this method, and I think it is one of the best.

In regard to the binding of the slides, strips of gummed paper can be bought for the purpose. I generally find them much too thick for the purpose; and gum is the very worst thing that can be used, for as soon as it is dry it tumbles off. The thing that I have found to answer the purpose is common paste, and better still if the paste is made the way I described in the 1879 YEAR-BOOK. The paper I find most suitable is black tissue paper. After the slide is mounted and cleaned, I take some thin shellac varnish, and varnish the paper binding all over; it is then almost indestructible for ordinary wear. It is a little more trouble, but it will be found well worth the little extra time that it takes.

THE APPLICATION OF ARTIFICIAL LIGHT TO PHOTOGRAPHY.

BY DR. DRINKWATER, F.C.S., ETC.*

The events of the past month have rendered necessary an apology on my part in introducing the subject of the use of artificial light in photography to your notice. I was asked to read a paper before the Society, and as I had devoted considerable time, especially of late, to the study of the various methods of artificial light, I chose this as a subject on which to say a few words to you this evening. Since so doing, I find I have been forestalled in more than one instance, as kindred societies have had similar papers read at their meetings, and, as far as I can judge from the reports of these meetings, the papers have been compiled by far abler hands than mine. I am afraid, therefore, gentlemen, I have not much in the way of novelty to offer you, but I may, perhaps, be able to give rise to a discussion from which we all shall benefit myself more than any of you.

Before proceeding to describe any of the methods that have been used for the application of artificial light to photography, let us enquire as to whether there is any need for its use, or if the need be so urgent as to cause the apparatus to be among the necessary impedimenta of the studio. Novelty is an aid to success in any calling, and no doubt the photographer who advertised photography by the electric light, and at all hours of the night, would do a roaring trade for a season; but when once the novelty had worn away the public would fail to see the advantage of having their likenesses taken at night, when the daylight would suit as well, and not cost so much, which is a matter of primary importance now-a-days. If there is no urgent necessity for carrying on portraiture by night—and I firmly believe such to be the case, except in rare instances—why need the subject attract our attention and take up our time? Artificial light in photography should not be used as a substitute for sunlight unless in the exceptional cases already alluded to, but as an aid to our work on dull and foggy days. Viewed in this manner the application of artificial light to photography has far more interest to the genuine artist than if merely looked upon as trade trick or advertising media by which one photographer can outdo his brethren.

In producing artificial light we have to follow certain natural laws, and no matter what method we pursue to obtain our end, these laws cannot be infringed. In the general usage of artificial illumination we have a large number of substances which are available for the purpose, all being easily governed by the laws I have alluded to; but in its application to photographic purposes our circle is limited, as the conditions to be fulfilled are more stringent, and two essentials are at least necessary for success, viz., *power* and *activity*.

For an illuminant to have power we require flame and luminosity, and before we can proceed to devise a method of illumination we must know something of the substance we are dealing with. Any solid or liquid substance which becomes liquefied or decomposed into gas at a temperature below that required for its combustion burns only in the shape of gas, and the light so produced we designate as flame. The three cones of this flame I need

* Read before the Edinburgh Photographic Society.

sarcely allude to, as they are well known to all of you. The two outer cones are of the most importance to us as photographers, they alone giving us luminosity. The old notion concerning the luminosity of the flame was that the high temperature along with the atmospheric oxygen decomposed the hydrocarbon, setting the carbon free in the solid state, and this being heated to incandescence emitted light. Many researches have been made, but though they have all tended to refute the above theory, they have not succeeded in explaining many of the phenomena connected with artificial light. As an example of this we cannot tell from an analysis of a gas what its candle power may be. It is now very generally admitted that the luminosity is due to the combustion of hydrocarbons, and that the degree of luminosity is infinitely connected with the density of the vapours contained within the envelopes.

Following out this theory, various methods have lately been proposed by which to increase the luminosity of ordinary gas by introducing the vapour of the higher hydro-carbons into the flame, but I will speak of these more fully presently. As regards activity little need be said, as very few, if any, artificial flames *per se* possess activity. They are all more or less yellow; but this difficulty can be easily overcome by passing the rays through coloured media, provided the luminosity is strong enough. A third requirement is also necessary for photographic illumination, viz., *diffusiveness*, for without this, luminosity and activity are comparatively useless. And this is where I am afraid the electric light fails; it is not diffusive, and in consequence we have very strong shadows.

Having thus glanced at the requirements in a method of artificial illumination necessary for photography, I will now refer to the various plans that have been tried, with more or less success, tracing the history, as well as I can, from the first experiment recorded in this direction up to the present time, when success has crowned the efforts of a few undaunted workers. As far back as 1852 we have records of attempts at photography by night, and several patents were taken out for divers methods, but they resembled one another very closely, being all devised on one common type. Some ordinary pyrotechnic composition was burned in a glass lantern, and the rays, having been rendered more actinic by passing through blue media, were diffused throughout the operating room by means of suitable reflectors. As you can easily understand, the disadvantages of such crude systems are many. The generality of the compositions used to burn in the lantern contain sulphur and oftentimes antimony, the fumes resulting from the decomposition of the burning mass being not only unpleasant, but dangerous to both operator and sitter. Inventors and improvers stepped into the field, but their efforts resulted in more or less failure, until M. Lombardi, of London, perfected an apparatus that is now seeking favour from the members of the profession under the name of the Luxograph. Through the kindness of Mr. Asher, the first photographer in Edinburgh who has had the enterprise to erect the apparatus in his studio, I was on Friday evening last permitted to see the instrument in actioui, and had the pleasure of being photographed by its aid. Two negatives were taken both of Mr. Dobbie and myself, and as negatives they were all that could be desired. I will pass round the prints for your inspection directly, along with some taken with a similar instrument by Mr. Turnbull, of Glasgow. Before doing so, however, let me describe the instrument. It consists, outwardly, of a large metal cylinder, slightly conical, and closed at the narrow end, or back, and nearly six feet in diameter at the other, the wide end, or mouth, the latter being closed by a screen stretched tightly over it, composed of what seems to be ordinary thin tracing paper, but is in reality a material called *papier minérale*, manufactured in Paris, and owing its peculiar semi-transparency to a certain mineral preparation, as its name implies. This screen is called the "dispersing screen,"

its use being to disperse the rays of light which pass through it, as we shall see presently, and which, without such arrangement, would, as in the case of the electric light, throw shadows of preternatural intensity on the picture they produced. If you can imagine a huge kettle-drum tilted up on its side, and fixed in such position with the head facing the seat whereon the sitter for his or her portrait is placed, you will have a notion about as nearly accurate as mere words can convey of the exterior appearance of the apparatus. The interior of the cone is lined throughout with some hundreds of small mirrors, slips of silverised plate-glass, thus constituting it an immensely powerful reflector. At the back of it, and in the centre, is a square lantern of blue glass of three different tints, open at the top, inside of which is placed an iron saucer or deflagrating dish, and access to which is had by a little furnace door at the back of the cone. The posing of the sitter, the "focussing," and general arrangement of the camera, having been made by ordinary gaslight, the *modus operandi* of the Luxograph is the simplest thing possible. An assistant takes out the deflagrating dish, puts therein from four to six ounces of a yellowish-looking pyrotechnic powder, and then returns it to its place within the lantern. All being ready, the powder is ignited. The ignited powder at once begins to burn with increasing intensity; and when the combustion has reached its acme, the face and figure of the sitter is flooded, and the room filled, with a beautiful soft violet light of a most diffusive and actinic character. From what I saw of the instrument I can certainly speak strongly in its favour, although I believe it can yet be improved both in its reflective powers, in the nature of its pyrotechnic composition, and in its management; but a little experience in its use will soon do all this, and an intelligent operator will have suggestions occur to him during his work which will ultimately render it a valuable aid to his art, especially in this uncertain climate. I cannot view the cartes which I have with the eye of a professed photographer, nor am I able, I fear, to judge of their artistic qualities fairly, but as far as I am able, I consider them perfect; and there is, I think, no sign which would enable anyone, however skilful, to pick them out from others taken on a clear summer day.

(To be continued.)

CLEAN PLATES.

BY F. A. BRIDGE.

I HAVE noticed on several occasions lately, in "Answers to Correspondents," you say "the marks you allude to are caused by dirty plates;" and only a few weeks back I noticed an advertisement offering, for a consideration, to supply an efficient method of cleaning plates.

Now, I have adopted the following plan for about seven years, and never spoil a picture through the plate being dirty, although some of my small plates (used for negatives for enlargements) have been used over and over again.

Fill a copper about two-thirds with water, and when it boils, put in a couple of packets of Manby's Cleansing Crystal; stir well, and while the water is still boiling, drop in your dirty plates *face downwards*. When the water has cooled sufficiently, take out your plates, and in nine cases out of ten the films will be left behind in the water. Rinse the plates well in clean cold water, and, while still wet, rub them over with Solomon's Diamond Polish (or tripoli and water with a little methylated spirit). I allow this to dry out, and when I require them for use merely rub it off (don't forget the edges) with one leather, and then give a final polish with another; but they may, of course, be clean and polished at once if preferred.

I may, perhaps, mention that I never use a substratum for dry plates, but I invariably edge my plates—large and small—with india-rubber in benzole, and I am never troubled with either dirty plates or split films.

I believe I originally got the idea of using Manby's Cleansing Crystal from the YEAR-BOOK or NEWS; but it is so long ago I am not sure about it.

EMULSION PLATES IN THE STUDIO.

THE imminence of the revolution in photography begins to be generally recognized, and we receive many communications on the subject, of curiously varying character. Many photographers hail, with pleasure, the prospect as a welcome change, whilst others, who, having mastered the wet collodion process, and fancying they saw in it "finality," were disposed to exclaim, "Rest, and be thankful," seem disposed to resent the coming change, and charge us with being a prophet of evil. Happily for themselves, however, the majority of our correspondents accept, with thankfulness, the idea of increased facilities for good and artistic work, at the risk of a little additional temporary trouble, and earnestly ask for aid in adapting themselves to new circumstances.

There is one class of correspondents for whom, we must confess, we feel considerable sympathy, although at times it is impossible to avoid a little amusement at their complaint. One gentleman writes: "I entered into photography as a profession twenty years ago, having been previously a miniature painter. I served no apprenticeship to photography, it is true; but I paid a handsome premium for instruction, and I purchased, at a good price, the studio, plant, and stock which an enterprising travelling photographer had twelve months previously established in our little town. My occupation as a portraitist was gone, and I was glad to spend the remnants of my little patrimony in thus averting ruin. For a time I did pretty well, by taking a superior class of glass positives, which, by my skill as a painter, I was able to finish pleasingly. Then came a "revolution" in the rage for *cartes-de-visite*; and I, who had never really mastered the negative process, was compelled to learn a new method, or rather, several, for besides learning how to take negatives, I had to learn to print. For many years I was full of troubles, and had just begun to feel tolerably master of my work, when another revolution was threatened. Carbon was to be king, and silver printing to perish. This was a serious trial, for my experience of the instability of silver prints made me feel it imperative upon a conscientious man to use a permanent process when one was available. I will not tell you of the heart-breaks and trials which experimenting with carbon brought me; suffice it to say, that eventually I conquered, and have been now for some time doing almost all my work in carbon. I am thankful that I adopted it, as it incidentally led me into doing, almost exclusively, a better class of work, at more remunerative prices: more pleasant and more profitable. But now, when the elasticity of youth is past, I am again disturbed with the cry of "revolution"! And, unless I am willing to be surpassed in the race, I must learn a new process, and learn to use new tools. Can you advise me: is it necessary? Can I safely go on adhering

to a process I know, walking in the old paths; or shall I try the new process, and if I fail, must I accept my fate, and, with as much dignity and patience as may be, betake myself to the calm retreat of the Parish Work-house?" As we have said, we cannot but feel some sympathy with our correspondent and such as he, although many will laugh. Within limits it is a picture, of course, of life in many trades and professions. The tide of progress and improvement inevitably sweeps away many victims in its progress. The hand-loom weaver was ruined by the introduction of power looms; the proprietors in the old coaching system were ruined by railways, and so with a hundred of other examples. Wise men accept the change and endeavour to adapt it to their purposes. Photography, as one of the youngest, but most rapidly progressive of arts, has inevitably seen many of those revolutions. A very serious one occurred a quarter of a century ago, when the Daguerreotype process was superseded by the introduction of collodion. We knew some who were so disgusted by the complete change in operations which was involved in the change, that they rather abandoned the profession than adopt the new methods. The majority, of course, devoted themselves with assiduity to mastering the wet process, and succeeded. And it is worthy of remark that, as a rule, those who had been most distinguished amongst Daguerreotypists, for the high-class excellence of their work in silver plates, soon attained to the same eminence in the production of negatives and prints by the new methods of working. This was also the case with carbon. Some of the best silver printers became the best carbon workers. The same promises to be due of the revolution now in progress. Some of the ablest workers by the wet process are already producing the finest possible negatives on rapid dry plates.

Many of our correspondents ask for advice as to whether we recommend them to produce their own plates, or to purchase them ready prepared. If the latter, whose plates we recommend; if the former, they ask for concise and definite instructions, as they are confused in the mass of information we have published. We fear that we cannot respond quite satisfactorily to all these questions. We may, without hesitation, recommend all about to try the new method to commence by purchasing plates ready prepared, and so reducing their risks of failure. We cannot recommend any special plate. There are three or four kinds of rapid gelatine plates now in commerce, and we have heard good reports and seen good results of all. In another column we print some valuable hints and advice from a very successful worker—Mr. Ferranti—who points out that as plates and developers can be purchased ready prepared, all that is left to the sagacity of the experimentalist is to follow carefully the instructions given. This advice is of the most vital importance. It should be the most simple and easy to follow. But, oddly enough, it does not seem to be so. We are continually receiving letters asking if they may modify the formula; what would be the effect of doing something or using something entirely different to that stated in the instructions. If the aim were experimental investigation, trial of such variations might be legitimate enough; but where the aim is practical success, nothing can be more unwise. As regards recommending some special process, or re-stating a special formula, we are equally unable to meet the wishes of some correspondents. In our last volume alone the fullest information is given, commencing on the second page, where concise, clear, and detailed instructions are given, and, at intervals of a few pages, continuously throughout the volume. Towards the close of the volume Mr. Bennett, who has been singularly successful in gaining extreme rapidity, gives his process in detail. We would advise the intending worker to read the various articles, then take one clearly stated process, and steadily work at it until success is attained; but to adhere throughout to instructions.

An important point to remember at all times is, that a new process involves new conditions, and that old experience, or experience with other processes, is often really misleading. We commend to beginners the article by Mr. Ferranti, and others he has been good enough to promise to follow. As the question of priority has been in discussion, we may mention that Mr. Ferranti commenced the use of dry plates in the studio upwards of nine months ago, and the examples with which he has favoured us are in all respects similar to prints from the finest wet plate negatives. Of the facility possible to be attained by skilful application for a few months, we may mention that in one day, a few days ago, Mr. Ferranti developed twenty-six negatives, all of which had been taken in from three to five seconds with a Dallmeyer 3B lens, not one of them a photographic failure. A manifestly important point is mentioned by Mr. Cobb, who has sent us some very admirable examples. He points out the danger of misappreciating the quality of the negative, as the appearance of a good gelatine negative does not resemble a good wet collodion negative. In the latter, visual opacity in the dense portions is a guide to printing opacity, whilst a gelatine negative may appear thin, but yet possess great printing intensity.

This is, however, but one amongst the variation of circumstances to be met. The photographer must be prepared for new conditions altogether; but he may rest assured that the results will well repay for the trifling additional study and care the acquisition of a new process may involve.

FRENCH CORRESPONDENCE.

THE MONITEUR UNIVERSEL AND THE PROCESS OF PHOTOCROMIE—THE PHOTOGRAPHIC SOCIETY OF FRANCE—THE SOCIÉTÉ FRANÇAISE DES ARCHIVES.

M. Vidal's Process of Photochromie in the Moniteur Universel.—Every day we who live in Paris are learning to appreciate more and more the services that photography in its different applications can render to the scientific and intellectual world. Among these applications are especially to be noted those to printing in fatty inks, the establishments for producing which are constantly multiplying and continually introducing improvements. In the first rank of these establishments the *Moniteur Universel* occupies a prominent place, for the managing directors of this journal have laid themselves out for working on their own account all the more important processes that have recently been introduced to public notice. By seizing and realizing the truth that the common processes of printing do not stand alone in their power to disseminate artistic ideas and productions, its managers have succeeded in making this establishment the principal centre for the publication of all the more important periodicals and illustrated literature. Many special branches have, from time to time, grouped themselves round the main stem of the institution, as, of old, huts and cottages were built in the neighbourhood of chapels, until they grew to be villages, and ended by becoming towns. Every kind of process for printing with fatty inks has one after another been introduced into and tried in the workshops of the *Moniteur Universel*, and, among such processes, none is more celebrated than the photochromie of M. Leon Vidal. This invention not only facilitates the reproduction of the numerous works of art contained in the public museums of Paris and France generally, but it also affords the means for bringing out magnificent illustrated publications with explanatory text to which the most eminent men in their own special lines have become contributors. In this way have been issued *Le Tresor Artistique de France*, and *L'Histoire Generale de la Tapisserie*, works that are real trophies of archæologic art. To make an undertaking of this kind successful, it requires to be under thoroughly sound and strong management; but though that of the *Moniteur Universel* complied with this condition, it seems that the

process of M. Vidal, admirable though it may be in its results, is more costly to work than was at first supposed. On this account, the requisite number of proofs for the illustration of the literary works undertaken by the directors of the *Publications Periodiques* could not always be furnished; besides which, the photochromic process has other faults which were only realised when it was worked on a large scale. Difficulties and differences have thus arisen between the inventor of the process and those who hoped to work it at a profit, and, in consequence, M. Vidal has separated himself from the staff of the *Moniteur Universel*. As far as he himself is personally concerned, this rupture is of no importance, for M. Vidal, a man full of resources, has already made arrangements for joining, as manager of their photographic reproductions, the house of Lemercier and Co., well known for the large part they have taken in the modern progress of the typographic art. But the question will naturally arise, whether the publications illustrated by means of photochromie will not suffer, as though the directors of the *Publications Periodiques* are endowed with sufficient energy and courage to enable them to endure any number of reverses, there are many interested in their valuable and artistic enterprises who are not without feeling unbusiness. There is no doubt that those works that they have undertaken they will carry out to the end; but will they be able to continue their illustrations by means of the photochromic process? As a general rule, nothing is more advisable than to quit the dangerous slope caused by an expense that is out of proportion to the profit; but the last numbers of a book that is published by subscription must be at least on an equal scale of beauty and finish with those of the first; unless, indeed, by the introduction of some more complete process, they can be made superior, for it is then only that those whose interests ought to be protected have no ground for complaint. For these reasons it is now contemplated to introduce, for the purpose of carrying on the works of the *Moniteur Universel*, the process of M. Germeuil-Bonnaud, of which I have spoken in my two preceding letters. This process for photographing in colours has the advantage of being much less costly than that of M. Vidal, and of being much more rapid in working. In fact, by means of it there is realised the direct association of colour with photographic action, for the layer of colour, and the photographic print which goes to complete it so effectually, form one of the same body. Henceforth we shall have no gelatine film to form—a film producing more than one inconvenience, for it is liable to swell unequally, or otherwise to deteriorate after a time, under the influence of heat, or of cold, or of moisture. It cannot be denied that the application of the method of M. Germeuil-Bonnaud would extricate the management of the *Moniteur Universel*, or of the *Publications Periodiques* (if the official title be preferred), from a serious predicament; but I am in great doubt whether they will have the opportunity afforded them. As I mentioned in my last letter, on the best authority, a joint stock company has been formed for working M. Germeuil-Bonnaud's process, and I may add, without fear of contradiction, that some of the greatest names in this country will be found upon its list of shareholders. Whatever the state of the case may be, however, I shall not fail to keep the readers of the PHOTOGRAPHIC NEWS informed on the subject.

Proceedings of the Photographic Society of France.—The presence of Mr. Woodbury, your distinguished fellow-countryman, was not the least of the attractions at the meeting of the Photographic Society of France, held on Friday last, the 7th inst. Mr. Woodbury was welcomed by the members present in a most flattering manner, and was received with all the honour due to a man to whom our art owes so many discoveries, but who is never content to rest upon his laurels. Of his continued researches he gave a further proof at the meeting itself, by exhibiting a new actinometer which he has recently designed. This consists of a small piece of apparatus the shape and size of a watch, provided with a circular frame divided into

sectors, which are coloured with the different tints impressed on photographic prints, from the lightest to the darkest shades. In the centre is an aperture through which the paper that has been exposed to the light can be examined, and an inference drawn of the actinic effect that has been produced: it is only necessary to compare the tint on the paper with those in the surrounding sectors to obtain a sure guide to the requisite length and degree of exposure. This new apparatus is much easier to work with than the actinometers generally in use at the present time; it is founded on the same principles as the old ones, but possesses very many advantages over them, which the photographic public will not fail to appreciate. M. J. Audouin showed a drying box of his own invention for drying plates in the gelatine processes. It is intended to act by means of a current of cold air produced through an aperture in the lower side of the box, that can be opened or closed to any required extent, corresponding to a chimney fixed on the upper side. There is an arrangement in this chimney for placing a lighted spirit lamp to produce a draught. The whole apparatus is as ingenious as it is practical: it is intended to accommodate plates of twenty-one by twenty-seven c. met., but any plates of a less size can be dried in it, as it is furnished with shelves on which they can be rested. Some photographs taken by aid of the luxograph were exhibited at the meeting by Mr. Harrison, and some others taken by various kinds of artificial light were also shown; but as they were not passed round, we had no means of forming an opinion regarding them. Among the other subjects of interest brought forward at this meeting was the declaration of the result of the prize competition for the best travelling camera; and also a communication sent by M. Magny on drawing films off the negative and transferring them to paper. The last subject on the agenda paper was a very valuable paper by M. Bary on the different substances that had been proposed as substitutes for yellow glass. This paper was illustrated in a most interesting manner by the projection on the screen of the oxyhydrogen lamp of the spectra of these substances.

The Societe Francaise des Archives Photographiques Historiques et Monumentales.—This society, which has now become firmly established, and largely extended, has succeeded in obtaining from the *Mairie* of the 9th *Arrondissement* of Paris the use of a hall for holding its meetings and exhibitions. Its first archaeological excursion for this season is fixed for the 6th April next, when photographic demonstrations and experiments will be undertaken. The committee of management of the Society has recently, at a meeting, drawn up a programme of most interesting excursions: this commences with an excursion to the valley of Charouse, a charming spot, not only replete with effects that satisfy the senses of the poet and the painter, but also rich in historic recollections. There are to be found in this valley bits that meet the taste both of the photographer and the archaeologist. Lying within easy distance of Paris, it has often been a source of inspiration to artists; it has the combined advantage of possessing magnificent woods and panoramic views, and at the same time curious out-of-the-way corners full of interesting associations. The value of these recesses, which are like sweets stored away in small boxes, is heightened by the fact that they are in the immediate neighbourhood of the celebrated *Chateau de Dampierre*, the residence of the ancient family of De Luyes.

THE USE OF DRY PLATES IN THE STUDIO.

BY C. FERRANTI.

FOLLOWING up several articles which have been published from time to time on this subject, it may prove useful to those who are desirous of investigating the properties of dry plates to know what has been gained by experience during the last six months. It is not desirable to enter into the merits or demerits of different kinds of plates produced com-

mercially, and consequently the information to be given must stand without these details. Without wishing to go quite so far as to say that nothing but "joy, comfort, and peace" will hereafter be the photographer's lot if he avails himself of the great advantages which are offered to him by the use of dry plates for his daily work, it can be broadly stated that by their use he can save himself much trouble and annoyance, and in many instances will be able to accomplish the hitherto impossible.

That a somewhat modified arrangement of dark-room will be necessary, and a little fresh experience acquired, before successful work can be relied upon, are not matters to frighten the most timorous, if they will bear in mind that the object to be gained is well worth the trouble. As an encouragement to beginners, it may be as well to state that plates and developer can be purchased. All that is left to their sagacity to accomplish is to follow carefully the instructions laid down. These ready materials are a great boon, which those only who have lived long enough to remember the time when to begin photography was also to begin a chemical manufactory can fully appreciate. The judicious division of labour has done a great deal for the rapid advancement of the art-science of photography.

Somewhat greater precautions than those generally taken to develop collodion negatives should obtain in the matter of dry plate work, but it is not necessary to place oneself in complete darkness. Naked gas-lights must be avoided, and the light, if practicable, admitted from the outside through a double thickness of ruby glass. Many slides can always be kept ready charged, and the development can be delayed for hours and for days to suit the convenience of the operator.

Development by the use of ferrous oxalate will be found to meet all requirements and to realize all expectations. This solution is used over and over again, and only requires very little attention to be kept in good working order. At first, the appearance of the plates is likely to prove misleading, inasmuch as greater density is necessary than in collodion plates, which do not alter much after fixing. Here is the case to say that a little experience will be useful.

To avoid frilling, an alum bath, composed of four pints of water in which four ounces of alum are dissolved, is used with complete success if the plates are plunged in it after washing, both after development and after fixing, before final washing. The best mode of drying the plates is to leave them standing on shelves covered with blotting-paper, and at such convenient distances from each other that the air can circulate freely between them. The next morning a little gentle heat from a fire (not from a gas-burner), applied to the back of the plate only, will complete the operation. When perfectly dry, these plates will be ready for retouching or printing, and do not require to be varnished, provided care be taken to keep them dry. Too long exposures generally give weak grey plates; the shorter ones mostly result in brilliant negatives.

Much more will have to be said in connection with this new mode of working which cannot find a place in this article, of which the aim is to assure those who are anxious to study an interesting and new phase of their art that they have nothing but pleasure to expect from their labours, while no great departure from acquired habits is needed beyond an easier and pleasanter way of working. The most conservative will be induced to try a process so little hampered by formulæ or technicalities. Professional photographers must welcome this valuable addition to their tool-chest, and will not be long in acknowledging that in point of execution the dry-plate holds toward the wet the position of the Martini-Henry rifle toward the old flint lock.

REFRACTORY STOPPERS.

BY F. A. BRIDGE.

SOME of your readers may find a difficulty in removing stoppers from bottles occasionally. I never knew the following method to fail. Hold the neck of the bottle in

the steam from the spout of a tea-kettle, and keep turning it round and round so as to heat the neck equally. In a minute or two (sometimes less) the stopper can be removed with the greatest ease.

I need scarcely say that when the neck of the bottle is thick, the heat must be applied more gradually than when the bottle is a thin one.

SOME EXPERIMENTS WITH THE GELATINE PROCESS.

BY H. HOULGRAVE.*

DURING November last there appeared in the *British Journal* two leading articles on the collodio-bromide process, in which the writers endeavoured to show the great advantages to be derived from reducing the quantity of pyroxyline in the collodion much below what is generally used, at the same time considerably increasing the proportion of silver bromide.

The conclusions arrived at were so remarkable that it occurred to me to try if the same principles would not apply to the gelatine process also, and my experiments have been so very satisfactory that I am desirous of bringing the matter before the Association at this early date in the hope that others may take it up, so that it may be thoroughly ventilated before the season for outdoor work arrives. The following will be found a good formula to begin with:—

Gelatine	26	grains
Bromide of ammonium	26	"	
Nitrate of silver	46	"	
Water	2	ounces	

This makes an emulsion which will be found to run through the filter and flow over the glass with unusual facility. Plates prepared with it give little trouble in development, and dry in about half the usual time. So far as I am able to test the matter at this present season of the year, these plates do not show the slightest tendency to blister or frill. How they will behave in this respect when warmer weather returns I fear is doubtful, as I think it may be taken as a general rule that the less gelatine an emulsion has in its composition the more easily will it be injuriously affected by water at a high temperature. Should, however, frilling occur—and this is the only difficulty to be dreaded—I entertain strong hopes that it may be entirely overcome by a judicious use of chrome alum.

The action of chrome alum on the gelatine film is very remarkable. If five drops only of a twenty-grain solution be added to two ounces of emulsion just before coating the plates, these when dry may be treated with impunity with water at 100° Fahr. Unfortunately chrome alum cannot be used in this way without some rather serious drawbacks, as it renders the film so hard and repellent that development becomes tedious and difficult, and the plates are particularly liable to a peculiar kind of stain. The sensitiveness is also materially reduced, and should the glasses be required for use again they cannot be cleaned in the usual way—that is to say, by merely washing with hot water.

All these difficulties, however, may be almost entirely avoided by combining a portion of glycerine with the chrome alum, and the following will be found a good method of doing so:—Dissolve twenty grains of chrome alum in one ounce of water, and then add half-an-ounce of glycerine. Now, having prepared an emulsion ready for immediate use, to each ounce drop in five drops of the above mixture, stirring at the same time with a glass rod, thoroughly but carefully, so as to avoid the formation of air-bubbles, and proceed immediately to coat the plates. Plates prepared in this manner will not stand water at the same high temperature as when the glycerine has been omitted; but they are quite safe at 80° Fahr., and that is probably quite sufficient for all practical purposes.

* Read before the Liverpool Amateur Photographic Association.

Correspondence.

DRY PLATES IN THE STUDIO.

SIR,—In your remarks upon Mr. Hazard's very practical and interesting paper you have, I think, made a slight and what, perhaps, may appear to be an unimportant error. It is there stated that Mr. Hazard is the first to announce publicly that he had abandoned the wet process in favour of the dry. Now it so happens that at a meeting of the South London, some time since, I made a similar statement, and showed results; but I am not aware that it was ever reported. If, therefore, there be any merit in priority, I beg to claim precedence of Mr. Hazard in the matter, as it was in consequence of what he considered my great success with dry plates for portraits that he was induced to "go and do likewise." Also see my letter in the *Photographic News* January 10th.

The introduction of dry plates into the studio for the purposes of ordinary portraiture is a subject which increases in importance every day, and doubtless will continue to do so as the season advances; for although this may perhaps be considered as being only the probationary period of dry plates in that direction, its general and speedy adoption is as certain to follow as that you yourself have more than once predicted it in the pages of the journal over which you preside. It is to be hoped that the Gamaliels of the art phases of photography will not allow this tidal wave of revolution to eugulf them, but that they will rise on its crest, and take advantage of this new power to its fullest extent; and then may we hope to see such things done as were never before dreamt of in our philosophy. I find that with those who take up this new method of working for the first time it is too much the habit to form an estimate of the negatives produced by comparing them with a good standard negative taken by the wet collodion process. This practice, however, is most misleading, there being but little in common between them; the only reliable test for a beginner is that of printing, and it is astonishing how soon he will become educated to the requirements of these new negatives.

My own experience tells me that over-exposure is the most easily besetting sin in the working of these new gelatine plates, and it is extremely difficult to produce anything like satisfactory results from such negatives. The prints enclosed are from negatives which have all been taken during the late most unfavourable weather for photographic operations, the plates having been supplied to me by Messrs. Wratten and Wainwright. I may add that I have not taken a single portrait otherwise than by means of gelatine plates for more than three months.—I am, sir, yours truly,

M. COBB,
Instructor of Photography,
Royal Military Academy, Woolwich.

[The insertion of the above was delayed through the Editor's illness.]

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

SIR,—A short time ago, I was engaged by one of our learned societies on a scientific expedition, part of my duties being to photograph the interior and exterior of lighthouses. During our survey, I was much impressed by the various means adopted to collect and disperse the rays of light emitted from oil-lamps and gas-jets, and resolved to try various experiments with these ingenious reflectors, and endeavoured to make them applicable to photography by artificial light. Thanks to the masters of numerous lighthouses, who kindly gave me great assistance, I am happy to say I have succeeded beyond my most sanguine expectations in producing a sharp and well defined negative, both by gas-light and paraffin oil, in fifteen seconds.

My draughtsman is now at work on the drawings, which I trust will be deposited in the Patent Office within a fortnight. Until then I cannot give you full particulars, but am prepared to challenge any system yet introduced of photography by artificial light, and place £50 in your hands to be competed for, if possible, at your office.

As I do not want to be bothered with a number of enquiries at present, permit me to subscribe myself the inventor of the

PERPETUAL PHOTOGRAPHIC PROCESS.

P.S.—I enclose a specimen of picture taken by my mode of lighting, on a Swan's plate, in five seconds. With an ordinary bath, the time of exposure is about fifteen seconds.

[No specimen was enclosed in our correspondent's letter.—Ed.]

Notes and Queries.

A CURIOUS PHENOMENON IN DRY-PLATE PHOTOGRAPHY.

DEAR SIR,—Lately I have been working with dry plates entirely in my studio in fact, have not used the bath for nearly three months, until quite recently.

Two weeks since, I was working with some plates. Seven quarter plates were taken on a very dull afternoon; but, to my surprise, upon developing, all the negatives turned as yellow as amber glass—this was with the ferrous-oxalate developer. Thinking it was a deposit of some salt of iron, I tried to clear it off with pure hydrochloric acid and water, one acid to seven water. This did its work very effectually, but as soon as the plates dried they were as dark as bottle glass.

Now these plates that had dried with no application of acid hydrochloric were still amber colour when dry, so I washed the surface over with water, and then applied the acid solution—this time to clear the whole film very nicely, and thus I saved some of the negatives. With the same developing solution, Messrs. _____ plates as well as some of my own preparing, turned out first-class. However, thinking something was wrong with the ferrous-oxalate developer, I made use of the pyrogallic acid developer, with just the same result—the negatives just as yellow as amber; so I was compelled to get several of my sitters to come again—this time to use wet collodion; with which, of course, the negatives were perfect.

Thinking that strong hydrochloric acid would act better, I tried. The first two applications all the yellow disappeared, and the third dose caused the film to dissolve, and that disappeared also. On February 18, I tried some more plates (pyro-development), according to the formula given in the News by Mr. J. S. Hazard. The picture developed very rapidly, beautifully soft, but that amber colour still made its appearance, and, worst of all, the plates now stand upon the shelf, all the films in a finely reticulated condition, and useless.

It is only right to state that I have many dozens of portraits taken upon the same plates really first class, also upon the plates of Messrs. _____ but for the present what dry plates I do use I shall prepare myself, and always have the bath at hand, in case of any mishap.

For out-door work, such as landscapes, or views generally, I prefer the common Becchey plates, which in my hands have proved all that the Canon says of them, and as a proof of such, I beg to enclose you eight views, two of the old church of Reculver, near Hern Bay; one of the Granville and Victoria Gardens; two of the renowned Granville Marine; one of Ramsgate Sands; one of the old Church, Minster, Thanett; one of Pinks Corner, Minster Lane, and a part view of St. George's Church taken on a plate with tea preservatives, and from these you will be able to judge for yourself.—Yours truly,

A. J. JARMAN.

WRINKLING OF GELATINE PLATES.

DEAR SIR,—Will any of your correspondents kindly inform me in your next PHOTO NEWS the reason of the following failure. I beg to say that I am working gelatine dry plates for C.D.V. portraits, and developing with pyro and ammonium, &c., and fixing with hypo, and am very well pleased with the negatives till they begin to dry; then the film wrinkles like a map, and cracks in a wet state, and the negative begins to lose the density.—Yours,

GRATEFULLY.

SPILLING HYPOSULPHITE OF SODA.

DEAR SIR,—In answer to an inquiry in the NEWS of last week headed "Notes and Queries," respecting the hypo in the cellar, I send you a simple remedy. If "Q. H." will cover the asphalt floor with dry wood ashes, and let them remain long enough to absorb the moisture, then sweep out with a dry broom, and have ready

a sufficient quantity of boiling pitch, and with a large brush give the floor two or three coats, I think he will have no difficulty in keeping our friend hypo down below.—I am, yours respectfully,
A PERFECT CURE.

CITRIC ACID IN THE SILVER BATH.

Will Mr. Valentine Blanchard kindly inform your readers where he purchases his nitrate of silver and citric acid that behave in the unchemical way stated? When a solution of pure citric acid is added to a solution of silver nitrate (neutral) as generally sold, no precipitate whatever should take place.

I should be happy to examine a few grains of these chemical for him.
CHEMICUS.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on the 6th March, at the Society of Arts, John Street, Adelphi, Mr. W. BROOKS, Vice-president, in the chair.

The minutes of the last meeting were read and confirmed.

THE CHAIRMAN said that since the last meeting the Society had sustained a very serious loss by the death of an honorary member of the Society, Peter Le Neve Foster, Esq., who had been an esteemed and valued friend to the Society; and it had been proposed and carried in committee that the President of the Society (the Rev. F. F. Sathan) should write a letter of condolence to the widow and family of the deceased, and he was sure that the whole of the members of the Society would fully endorse what had already been done in committee.

MR. ALEXANDER COWAN was proposed and elected member of the Society.

MR. FOXLEE asked whether it was the intention of the Society to discontinue sending to members the post-card notices of the meeting.

THE CHAIRMAN said that it was the intention of the Society to discontinue sending them, and members would always find notices of the Society the week previous to the meeting in both the PHOTOGRAPHIC NEWS and the *British Journal*.

A paper was then read by the Secretary from Mr. W. J. ANKORN, on "Imitation Porcelain Transparencies."

MR. R. V. HARMAN read a paper on "Artificial Lighting" (see page 122).

THE CHAIRMAN said he had seen portraits taken by artificial light in a much less time than Mr. Harman stated. He had seen a fully-exposed cabinet portrait taken in sixteen seconds, which was less than half the time mentioned (thirty-five seconds).

MR. CLARKE (Messrs. Alder and Clarke) then handed round for the inspection of the members some specimens of portraits taken at a fancy dress-ball at Chelsea, which were very much admired by the members; he stated that the negatives were taken on the average of eighteen an hour; the exposures were from two and a-half to seven seconds, gelatine plates being used. He would also call attention to the extreme softness in the shadows. Prints from many of the negatives had the appearance of being highly retouched; but such was not the case. The bust and vignette heads had been taken in various parts of the country these were taken by the ordinary wet collodion and bath process with exposure from twelve to seventeen seconds. He generally used himself a Dallmeyer No. 2b, with about the second stop.

THE CHAIRMAN remarked that the softness of the shadows and lines in the face could be accounted for, the source of light being low and diffused; whereas in an ordinary studio he always considered there was too much top light used from the skylight. It might be remembered by some that some few years ago he had remarked that the reason why people in photographs as a rule had such a bad expression was, in his opinion, due to using the top light, and that scarcely any person was ever seen under the same conditions of light and shade except in the photographic studio; and until such a system was adopted as that the light was the same as the light persons were generally seen in, exceedingly unnatural expression would invariably result; and he might add that he had noticed that, as a rule, the lower the source of light, the better would be the expression. And it was highly essential, in using these artificial lights, to have a flue with plenty of draught to carry off the poisonous fumes.

MR. BOLAS stated that the best plan he had found, as he had stated before, was to have a suitable place built outside of a window, so that it would not then be possible for any of the highly poisonous

fumes to enter the room, but thought it would be advisable to give notice to the fire engine station in the neighbourhood that things were all right.

Mr. A. L. HENDERSON said he remembered well many years ago, when he was using artificial light of a similar kind, for taking positives on glass, that several times he had several fire-engines at his door, which became a nuisance.

Mr. JACKLETT stated that he was using Moule's lamp, and his average exposure for cartes was twenty-five seconds with Dallmeyer's 2B with the second or third stop, using the wet collodion process.

Mr. HARMAN, in his reply, said it must be understood that the specimens he brought were the results of his whole experience in artificial lighting, and not as specimens of photography, and it could be easily seen that there really was something in it. The whole of the apparatus that he employed were very rude, and did not cost more than five shillings at the utmost.

Mr. A. L. HENDERSON said he had worked Moule's lamp successfully for busts and vignette heads, but considered it a failure for full-length portraits, the lower part of the picture always being much too dark to be in harmony with the other part of the picture.

Mr. ANCKORN stated that he was making an apparatus in tin which he hoped to have finished shortly, and would then give a description of it.

Mr. BOLAS asked whether any gentleman had tried three lights in different positions—for instance, one above the other.

Mr. BRITTLEBANK said he had just constructed a simple machine to burn twenty thicknesses of magnesium ribbon at a time, and found it answered perfectly without any clockwork; by slowly turning a handle it worked effectively.

Mr. F. A. BRIDGE asked how he (Mr. Brittlebank) managed to light twenty ribbons at a time.

Mr. BRITTLEBANK, in reply, said he always kept an ordinary bat's wing burner fully on, which lighted the ribbon in the first instance, and kept it burning continually, and he found no difficulty whatever.

Mr. AYRES exhibited some very ingenious apparatus for copying photographs, &c., whereby they were always in position in the centre of the lens, and square, which saved a lot of time being wasted. He also exhibited a contrivance for holding a negative, and masking any part of it—for instance, to copy a single figure, or any particular part of a large negative.

Mr. HARRISON also exhibited one of similar construction.

Mr. HENRY wished to call the attention of members to a dark slide having a shutter without hinges, by having a small spring fillet in the edge of the camera, so that when the shutter was withdrawn, the spring piece closed the opening; it could readily be adapted to any camera.

Mr. F. YORK handed round for inspection two negatives which Mr. Brooks had enlarged for him from small negatives (the enlargement being nearly three and a-half in diameter). He was quite surprised at the results. They were done by the wet emulsion process, the subjects being some of the animals in the Zoo, which he considered very little inferior to original negatives.

Mr. F. A. BRIDGE read a paper on "Finance," which was rather humorous.

Mr. CLARKE consented to read a paper at the next meeting on his "Experiences in Photographing at the Fancy Dress Ball."

Mr. BRITTLEBANK also promised a paper bearing upon "Artificial Lighting."

A vote of thanks was then passed, thanking the gentlemen who had contributed to the evening. The proceedings then terminated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The fifth ordinary meeting of this Society was held in 5, St. Andrew Square, on the evening of Wednesday, the 5th instant, when the President, Mr. LESSELS, occupied the chair.

The following gentlemen were unanimously elected ordinary members of the Society: Messrs. Robert Pearson, James Bertram, William Johnston, John Rattray, Thomas A. Croal, and William Dougall.

Dr. THOMAS DRINKWATER, F.C.S., then read a paper entitled "Notes on the Use of Artificial Light in Photography" (see page 124).

The PRESIDENT, in the name of the Society, thanked Dr. Drinkwater for his interesting paper, and invited Mr. Asher, whose name was prominently connected with the matter in the paper, to open the discussion.

Mr. ASHER said that, from the limited experience he had had with the Luxograph, he was not prepared to enter into minute details; but he was fully satisfied that the apparatus was capable of producing the work claimed for it by the patentees.

Mr. BASHFORD said he had been much interested in Dr. Drinkwater's paper, more especially in that part treating of the recent advances in gas illumination. The alba-carbon exhibited by Dr. Drinkwater was an attractive novelty. Mr. Bashford could not agree with the statement that a blue medium would impart actinism to an artificial light efficient in that property, as if a light did not primarily possess sufficient chemical power its passage through blue or any other media would simply modify the intensity of existing rays without adding to them in any way. In regard to the form of reflector, he fancied that a true parabola which reflected parallel rays would tend to produce heavy shadows, whereas diverging rays impinging on surrounding objects, and reflected from them, would help to remove this stumbling-block in the way of artificial illumination. Through the courtesy of Mr. Asher he had on the previous evening had an opportunity of witnessing the luxograph in action; and with an exposure of about twelve seconds had taken a whole-plate negative, which, with four prints from it, were handed round for inspection. The prints possessed distinctly different characteristics, and showed that the negative was one from which any desired result could be obtained, a quality highly valued by all intelligent printers.

Mr. W. H. DAVIES said the past history of the Edinburgh Photographic Society showed that it had devoted more attention to artificial illumination as an aid to photography than any other Society. Sixteen years ago, Sir David Brewster (then the President) and Mr. W. Neilson had their photographs taken in the same room in which he was speaking, by employing pyrotechnic compositions, and also by ordinary house gas, and the Society's albums contained prints from negatives produced on these occasions. The Society, many years ago, had before it a Moule's Photogen, and the apparatus was still to be found in the cellar of one of its members. Speaking from recollection, this old apparatus combined all the essential elements of the more recent Luxograph.

Mr. J. M. TURNBULL corroborated the remarks of Mr. Davies in reference to the Photogen, and said that in his opinion artificial lighting for photographic purposes was as far advanced twenty years ago as at the present day. He agreed with the remark that a coloured medium, simply acting as a filter, obstructed some illuminating or other rays, but in no sense added actinism to the light.

Mr. M. G. DOBNIK said that although a patent apparatus had been constructed twenty years ago, the very fact that it had become obsolete was evidence that it was unable to produce satisfactory work, and hence it never gained for itself a permanent position. Since that time, scientific knowledge had developed the idea, and the results, as exhibited by the prints on the table, gave ample evidence of the practical value of the latest outcome of these investigations.

Mr. W. NEILSON said that he had still a very vivid recollection of the toasting he got on that memorable night mentioned by Mr. Davies, and the effects of which were visible on his cheek for nearly a fortnight afterwards. He considered the photographs not equal to those obtained by sunlight, and in his opinion pictures taken by artificial light would never favourably compare with those taken in the usual way.

Mr. CRAIG-CHRISTIE expressed himself highly gratified with Dr. Drinkwater's paper, and suggested that possibly one of the hydro-carbons possessing more carbon than those hitherto experimented on, for illuminating purposes, might be found to lend itself to the perfecting of ordinary gas for photographic purposes.

Dr. DRINKWATER replied that carburetted hydrogen was only capable of consuming a certain proportion of carbon, and that if that amount was exceeded, the light was impaired, and a smoky flame resulted.

Mr. J. M. TURNBULL next exhibited an ingenious modification of the spirit lamp, and its adaptability to heating purposes where a Bunsen would generally be used when gas was available.

The lamp consisted of a reservoir, connected by a flexible or rigid tube to a wick-holder. The latter had an outer tube so constructed that by a slight turn it would remain at any height above the wick-holder, and so controlled the consumption of spirit and the size and heat of flame.

The lamp was shown attached to a Chadwick's "Oxygen Generator," and was quite as effective as the patent Bunsen originally supplied.

Mr. W. H. DAVIES laid on the table Thompson's recent work on

Cyprus, and also Rosatti's views in the same island. After these had been examined, votes of thanks terminated the proceedings.
W. J. BASHFORD, Hon. Cor. Sec.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Association was held at the Museum, Queen's Road, Bristol, on Wednesday, the 6th instant, Mr. T. DAVEY in the chair. The minutes having been confirmed,

Mr. STEVENS, thinking that there might be some present who had not seen the little pocket camera called a "scenograph," had brought one with him. He remarked that all three of the legs being rigid was a great drawback, as it rendered it almost impossible to stand it on a piece of very sloping ground, the danger of its falling over being too great. This was a great fault, and required remedying before it could be looked upon as at all perfect.

The CHAIRMAN thought the camera very light and portable, but feared it partook more of the character of a toy than of a piece of apparatus for really hard work. It was certainly very light, but he feared that that extreme lightness was in some respects against it, as with a more solid camera buildings could be photographed if the wind were blowing a little, but he thought the slightest breeze would cause the scenograph to vibrate.

Mr. H. A. H. DANIEL said he thought the nicest thing about it was the ball-and-socket head to the stand. He then reverted to the subject of nitrate bath-holders, and stated that he had used an ebonite one for some time, being so pleased with it on account of its lightness. He feared, however, that his opinion had changed, as some little time since his ebonite bath had cracked, even with careful usage. He had it repaired, a complete strip of fresh ebonite being placed over the fracture. Notwithstanding great care this had also cracked, so that he feared ebonite baths were not strong enough for use out of the darkroom, in which place their lightness was of the least value. When last in London, he called at Mr. Moore's, in High Holborn, and saw the india rubber-lined wooden baths he advertised, and could not help fancying that in them the right thing had at last been discovered. They were light and yet very strong, and were, of course, perfectly harmless to the nitrate of silver, being lined with pure rubber.

Mr. E. BRIGHTMAN could quite endorse Mr. Daniel's remarks, having lost the whole of a bath last season through the ebonite holder breaking. He had now purchased one of those spoken of by the last speaker, and was much pleased with it.

Mr. POWELL (of Bath) asked if anyone had seen the wood dippers, made in such a manner that the plate could be inserted and drawn out of the bath face down.

Mr. BRIGHTMAN replied that he had, and explained the mode of making the catch for the top of the plate.

Mr. DANIEL said he saw one in use for large sizes last summer at Lynton, and the owner expressed his opinion as to its great usefulness.

Some further discussion on the places that would most probably be visited during the coming summer concluded the meeting.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The proceedings of the meeting of this Society held on Tuesday evening will appear in our next. We have not space in the present issue for the report, which, in the absence of the papers, is of slight interest.

CETYWAYO THE USURPER (from a Fashionable Standpoint).—She was a Shop-window Beauty—a Photographer's Pet—a Charmer of the Camera; and though her likeness was frequently but a negative delight, her life was a positive pleasure, for she basked in the rays of popularity. But one morning she was taken with a fit of melancholy. Her husband observed it. She had, as he well knew, been previously taken with a befeater hat, taken with a bird, and taken with a parasol. In order to comfort her he now took her hand—a very pretty one—which would have gained even the admiration of the fastidious Louis Cartier, and exclaimed: "Oh, confide in me, beloved one! Pour all your grief into my bosom. A husband's bosom especially

lens itself to such uses. Tell me everything, my more precious than silver-Bathsheba!" "My heart is very heavy, love," she replied. "Could you but see it, you would call 'Loadyun!'" Such are the aberrations of grief. She meant collodion. "Not I, of all-bu-men, if I thought 'twould add to your distress. Tell me your cause of sorrow, my sweet one, *s'il vous dry-plate*," he implored, speaking French with an English accent in his agitation. She yielded. "I mourn," she sobbed, "because last week the dreadful burglar person sold two hundred more than I did, and—and—*this week that quite too awfully ferocious-looking Cotywayo is going off better than either of us!*"—*Funny Folks.*

PHOTOGRAPHIC REPRESENTATION OF MOTION.—The *English Mechanic* says:—"It is known that Mr. Muybridge, of San Francisco, has recently succeeded in taking a large number of instantaneous photographs of the various attitudes assumed by a horse in motion, even when galloping at the rate of nearly twenty metres in a second. These figures are reproduced in *La Nature*, Dec. 14, and are of great interest in many ways. Some of the attitudes are very unexpected. M. Marey, whose researches and apparatus have thrown great light on animal movements, has been much struck with Mr. Muybridge's figures, and invites him to give his attention to certain problems of physiology that are difficult to solve by other means. One of these is the flight of birds. He suggests the idea of a kind of photographic shot seizing the bird in an attitude, or better, a series of attitudes, showing the successive phases of movement of its wings. Mr. Muybridge has shown his ability to do this. What beautiful zootropes (M. Marey also suggests) might be obtained by the method! We might see in their true paces all sorts of animals; it would be a kind of animated zoology. As to artists, it is a revolution for them—for it furnishes the true attitudes of motion, those positions of the body in unstable equilibrium which a model cannot pose in."

To Correspondents.

PLATINO.—We have had no personal experience with the platinotype process, but have published all the available information on the subject. We regret, therefore, that we cannot help you. One of the difficulties of a patented process is, that there is little temptation to experiment with. None but licensees are expected to practise the process, and they are supposed to receive full instructions from the licensee.

ARTHUR GYNNE.—In our last volume you will find various detailed articles, containing precise instructions. One on p. 2, and again on pp. 513 and 524, occur to us as containing valuable hints. There will shortly be other articles on the subject. A paper was read on Tuesday night at the Photographic Society, which will appear in our next.

J. L.—We regret that we do not know of any one who is likely to supply Pellet's paper commercially. 2. The chief cause of negatives becoming stained with silver from contact with sensitive paper in printing is the paper being placed in contact when the paper is slightly damp. Such stains may be easily removed by means of a tuft of cotton wool and very strong hypo solution or weak cyanide, and then rubbing with clean water.

W. W.—We do not know where you can obtain the emulsion in question, as it was made by Mr. Brooks himself. By ordering it you could no doubt obtain it. Possibly Mr. Brooks might be willing to prepare you some. There is a difference between the results of moist emulsion and dry emulsion. We cannot tell you whether bath plates would produce similar results. It may be worth while to try.

G. TAYLOR.—It is very difficult to remove the varnish from a negative, as it is not merely on the film, but in it, permeating the whole structure. Soaking and repeated flooding with strong alcohol is the only agent you can with advantage use. A strong solution of ammonia may be used, and sometimes answers. We prefer to reduce the density by the use of alcoholic solutions. 2. We know nothing of the gentleman your name, beyond the fact that he has, we understand, been for some months out of town.

COLLODION.—The defect you describe might proceed from a variety of causes. Thinness of image is often the result of using newly iodized collodion: when the collodion becomes a little more mature, the negatives may possess more vigour. Or it may arise from the collodion being somewhat thin or wanting in body from the use of insufficient pyroxylene. A variety of other causes might also produce a similar result.

R. W. THOMAS.—Many thanks. We shall probably have a note on this subject in our next.

WARWICK BROOKS.—Thanks. Some remarks in our next; several correspondents in our next.

The Photographic News, March 21, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

GELATINE PLATES WITHOUT GLASS—A NEW USE FOR COLLODION—MAP-MAKING IN FRANCE AND AUSTRIA.

Gelatine Plates without Glass.—The continued employment of gelatine plates in the studio, as well as out-of-doors, naturally sets one thinking about the improvements we may, in the end, secure by throwing over collodion. If gelatine in a dry state can be universally used for the sensitive film, why cannot we employ the material prepared in the form of sheets of a tough and transparent character, and thus do away with the use of glass? There should be no reason why this could not be done. If the gelatinous bromide film cannot be toughened by the admixture of alum or other substance that might interfere with its qualities as a photographic body, then the strengthening and toughening can be easily carried out by mechanical means. For instance, a layer of leather collodion—or, in other words, a collodion to which a small quantity of castor oil has been added—would make a capital support, and render the films at once capable of manipulation without risk. Imagine a traveller setting out with films of this kind, a stock that weighs comparatively little, and without any risk from breakage. Hundreds of such gelatine sheets might be packed together, and guarded far more easily from the light than dry films on glass. Possibly, the machinery used for rolling gelatine, and which has now reached a high pitch of perfection, could be brought into play, for under these circumstances the surfaces are made as smooth and even as glass. Could this be done, we should have solved the problem which, for many years past, has been set before photographic experimenters to propound by the Vienna Photographic Society. One of the Voightlander gold medals has, for some time, been offered by that Society to whomsoever should produce a transparent pellicle, either to replace glass in negatives, or render that vehicle unnecessary for work in the camera; and if a tough and sensitive gelatine film can be prepared, there is no reason why the producer thereof should not claim the medal as his right. So far as our experience goes, the principal difficulty in respect to these gelatine plates is not to expose them too long. We have some plates in our possession that have now been kept for four months, and these proved over-exposed in taking a portrait with a period of twenty-five seconds at a time when thirty seconds would have hardly sufficed for a wet plate. By curtailing the exposure yet another five seconds there was a marked accession of brilliancy, while no lack of detail could be discerned. Some difficulty may be experienced at first by the necessity of developing in a dish, but dry plate workers are used to this, if portraitists are not. The drawback to developing a gelatine plate in the hand, or upon a pneumatic holder, is that if the process is rather long, it is apt to become tedious, and the operator is tempted to hurry; while, again, any dust particles flying about, if once they settle upon the gelatinous film, are not to be removed by washing. The latter difficulty at once disappears if you keep the film covered with the developing liquid in a dish, and you can then allow plenty of time for development; there is, however, the drawback that the plate is not so ready for examination against the light as when it is held in the hand.

A New Use for Collodion.—Collodion has lately been brought prominently forward as a material for capsules. It is not unsuited for such a purpose, although when upon the bottle the capsule, maybe, appears rather more useful than it really is. The stoppered bottle is simply dipped into a vessel of collodion and bronze (or other pigment), and in this way capsules of brilliant finish and of any desirable colour are furnished. If the bottles are not subjected to very rough usage, no doubt collodion capsules, provided the collodion is properly prepared, would answer

the purpose of protecting the cork from damp; but they would be liable to damage from abrasion. For this reason, however strong and metallic they may appear, a collodion capsule is hardly likely to supersede those of lead or tin with which we are familiar. A tough collodion, and not a pulverulent one, is, as a matter of course, the best for this purpose, and we have no doubt that the addition of a little castor oil would improve its consistence. Now that photographers, turning their attention to gelatine plates, are likely to have less to do with collodion, it would be well indeed if other demands should arise for this important material.

Map-Making in France and Austria.—The French Government, according to our Paris Correspondent, is making good use of photography in improving the maps of the country. There seems to have been a difficulty, inherent to a military state like France, in getting two departments to work together, a civil one and a military one. Henceforth, since France has now placed civilian power above military, and reversed the previous order of things, there will doubtless be less difficulty in fusing different departments; but a long time has been necessary, we are told, to bring this about in the present instance. There were excellent maps in the Staff Office of the French War Department, but as this office does not recognize officially the designs and transactions of the Department of Roads and Bridges, which is a branch of the Home Office, the latter had no means of obtaining these maps. When, however, the inexorable rules of officialdom had been satisfied, then it was necessary that the Ordnance maps should be put on a scale suited for being corrected by the various civilian road-surveyors, and to do this the aid of a photographic establishment was invoked. The civilian surveyor of every district will receive a map—or, rather, a sheet—all of which will be on the same scale, and upon these all the necessary changes will be noted, where new ones have been made, where old ones have been closed, or where woods have been cut down. Things which were of no importance to the military surveyor will be noted and entered by the civilian, and in this way France hopes to secure in time a map equal to that produced by the German military engineers. In Austria they are also making considerable use of photography in map-making—not, be it understood, simply as an aid to the metallic engraving of the map, but in lieu of engraving altogether. Large maps with clear black lines are, in the first place, prepared by a draughtsman, and this is afterwards photographed in several sizes, and put upon stone or zinc for printing from. The plans being in the first place specially drawn for photographing, very clean negatives are the result, while the time and expense thus saved, by doing away with engraving upon metal, is something marvellous. So far, we believe, Austria is the only power which makes such extensive use of photography; but the art is, as our readers know, applied in one way or another at most geographical institutes in this country and abroad. If we mistake not, photo-lithography has likewise been much used lately in the production of some small popular maps selling at extremely low prices in the metropolis just now. Being reduced from engraved originals, their fine lines were occasionally a little rotten and intermittent; but these defects would not be forthcoming in the case of photo-lithographs prepared from originals specially drawn for the purpose.

GELATINE EMULSION PROCESS.

BY C. BENNETT.*

I REGRET that in bringing this matter before you this evening, in response to an appeal from the Assistant Secretary, that I have so little that is new to introduce to your notice beyond what I have already published. But in view of the

* Read before the Photographic Society of Great Britain.

extraordinary interest which is evinced at the present time—an interest which appears to be increasing daily—in all that is connected with gelatine emulsion, I trust you will permit me to refer to one or two points to which I attach the greatest importance in their bearing upon the future of this process.

My attention has been chiefly directed—as many of you are aware—to the production of the highest degree of sensitiveness attainable; but while keeping in view the main object, I have not lost sight of what is equally desirable—*quality of result*. In order to secure the combination of these two qualities, I recognized the necessity of a strict adherence to one leading principle, namely, the thorough elimination of every cause which might lead to the production of fog, however slight, either in the emulsion itself or in the prepared films. This idea was embodied in the formula and directions I published some twelve months ago, and I will now proceed to explain the reasons upon which my process—if process it can be called—was based.

In the first place, I will speak of the salting of the emulsion. It is very possible that opinions and tastes may differ with regard to the best proportions of silver bromide and of gelatine which should be contained in each ounce of emulsion, and it is a matter to which I do not attach paramount importance, though, as the result of very numerous experiments I prefer, the quantities given in my formula of last year. But I insist, for reasons I shall state, that the relative proportions of soluble bromide should be such as to leave a decided excess of the former in the finished emulsion. This, I am aware, has been recommended by others long ago; whilst, on the other hand, some writers have stated a higher degree of sensitiveness to be obtained by fully converting the bromide or by having the silver in excess. Without denying the possibility of using a fully converted emulsion, or even one which has contained free silver, I strongly deprecate such a course, for besides introducing difficulties which do not exist in the working of an emulsion made with free bromide, the use of the full equivalent of silver nitrate is not only unnecessary in order to obtain the highest degree of sensitiveness, but it actually defeats the object in view. The more palpable difficulties which it introduces consist in the extreme tendency to fog and abnormal reduction under the action of the developer, and the absolute necessity for the use of restraining bromide, and also the great care required at every stage of the operations, even when comparatively long exposures are to be made.

But in addition to these, there appears to be a danger of the formation of an organic compound of silver and some portion of the gelatine, which suffered reduction even though un-exposed, causes, in many cases, the defect known as “red fog,” while in other instances it takes the form of a general veil, obliterating all the fine details, and rendering anything like strong or forced development a matter of utter impossibility.

Now, if the relative proportions which I have previously laid down—seven grains of ammonium bromide to eleven grains of silver nitrate—be adhered to in all cases, whether the actual quantities recommended in each ounce of emulsion be altered or not, there is no danger of the formation of this deleterious compound; and provided that due precautions are taken in other respects, the films prepared from such an emulsion will be found capable of any degree of forcing with a developer entirely devoid of restraining bromide, and containing such a quantity of alkali as would inevitably fog an emulsion prepared with excess of silver.

There is one feature I have noticed in connection with the complete saturation of the soluble bromide, viz., that after passing the point I have named, the nearer we approach the full equivalent of silver, the thinner and more transparent do the films become; in fact, with the

full quantity of silver, the dried film scarcely appears to contain any bromide at all, though actually it contains more than the denser films obtained with my formula.

The next point which deserves my notice is the necessity for using, as far as may be possible, a perfectly non-actinic light, both in the preparation of the emulsion and plates and in the development. It is some years since this requirement first attracted attention in connection with bromide plates, but the full extent of their susceptibility to the action of rays of low refrangibility has only recently been fully recognised, and it is a question at the present time whether it is possible to preserve gelatine films from actinic action under any circumstances short of complete darkness. To work under the latter condition is an obvious impossibility. All that can therefore be done is to reduce the chances of actinic action to a minimum, by using, as I have directed, two, or even three, thicknesses of ruby glass in the window of the operating room, and to expose the sensitive preparation as little as possible to the small amount of light thus obtained.

The reason of this is obvious, namely, to preserve the plates scrupulously from the influence of all light except that which passes through the lens to form the picture; or, in other words, this is another safeguard against fog—in this case produced by actinic influence as distinguished from the chemical fog arising from free silver.

If such precautions are observed in every stage of the operations as to lead to the production of a film absolutely free from any trace of incipient fog or veil, the restraining action of the gelatine in combination with the silver bromide will be sufficient to protect it from any abnormal reduction under the most powerful development. It is questionable whether in practice it is possible to prepare a film which is absolutely free from every trace of fog; if such were possible, we should no doubt find the sensitiveness of these plates only limited by the strength of the developer it was possible to apply to them. Without going to the extent of *absolute* freedom from fog, if the directions I have given as to the arrangements of the light be strictly attended to, the result will be films which are capable of outstanding the action of what would have been considered a few years ago an *impossible* quantity of ammonia, and that *without the addition of the slightest trace of bromide*.

I cannot lay too much stress upon this matter of the thorough elimination of fog, as upon that one point hinges the whole question of sensitiveness—in gelatine plates, at least. There seems reason to believe that these plates differ from others in this respect, that the most feeble actinic impressions may be rendered visible by the exercise of a little care and patience, combined with the use of a sufficiently strong developer. The members of this Society will, I doubt not, fully appreciate the fact that if the film be veiled or fogged, be it ever so slightly, during the preliminary operations, the defect will be brought to light by a strong developer, when it might probably escape a weaker one. The application of such a film is therefore limited—its practical sensitiveness deteriorated; for evidently the useful action of the developer must cease at the point at which the veil or fog comes within its power, all actinic action below that point being lost in the general reduction.

I will now allude to the chief feature in my process which *directly* affects the sensitiveness, namely, the extension of the period during which the gelatine and salts are allowed to emulsify or ripen. I have in my own practice carried this emulsification to a period of seven days, with the result of obtaining a continuous augmentation of sensitiveness, accompanied, as might be expected, by an increased necessity for care in the treatment of the emulsion, and a greater liability to fog. With only three days' emulsification I have been enabled to produce results ten times

more rapid than any previously considered impossible—certainly no one had even produced, possibly ever attempted them; and I believe success to be impossible even now, unless my mode of working be followed closely.

This system of prolonged emulsification has been objected to on the ground that it is troublesome, unnecessary, and leads to the formation of an emulsion which is unmanageable from its tendency to fog.

With regard to the first charge, I need say but little: if special results are sought for some little extra trouble must perforce be incurred; but, after all, the extra trouble in this case is slight, if the operations be reduced to a system. As to the statement that prolonged emulsification is unnecessary, I repeat that the very highest degree of sensitiveness is *only* to be obtained by its means. Those who do not require that extreme degree, may content themselves with hours instead of days. Finally, the resulting emulsion only becomes unmanageable when the other rules laid down are shirked. We cannot expect an exquisitely sensitive film to work in a perfect manner if submitted to the comparatively rough treatment which might suffice for a plate twenty times less rapid. If my directions be followed *in their entirety*, gelatine bromide emulsified for the full period of seven days will be as free from fog as one which has undergone but as many hours.

In conclusion, what I claim in connection with my process or mode of working, is the recognition of certain conditions which are absolutely necessary of observance in order to work gelatine emulsion to the greatest advantage.

For some years gelatine has been said to far exceed wet collodion in sensitiveness, but the statement had not been borne out by published results. It was said that gelatine plates could be prepared of such exquisite sensitiveness that it was impossible to use them. Why? Simply because the true conditions under which such plates require to be used were not recognised, or, if recognised, not put into force.

THE APPLICATION OF ARTIFICIAL LIGHT TO PHOTOGRAPHY.

BY DR. DRINKWATER, F.C.S., ETC.*

THE subject of patent law is too sore a point, and would entail too much time, to go into this evening, but I cannot help expressing an opinion that the Luxograph is a patent that can be very easily infringed when we remember it is only an improved modification of the very process which I alluded to at the opening of my paper, the patents for which have expired long ago. This is, however, a subject that we shall no doubt hear more about in a little. After pyrotechnic compositions had failed in fulfilling the anticipations of the inventors, metallic magnesium was tried, and with what at first sight seemed like success. The most perfect lamp for the production of this light was that invented by Mr. Brothers, of Manchester. It consisted of an arrangement by which three ribbons of wire were simultaneously burned, and the light so produced was reflected on to the sitter by parabolic reflectors. The light so produced was both diffusive and actinic, but the expense attending its use was a great drawback, and after a short-lived existence the magnesium lamp and belongings passed into the retirement already sheltering its pyrotechnic companions, from whence, perhaps, some day it will be fished out and landed as a new invention. One of the objections to the application of almost any powerful light to photographic art is the proneness to strong shadows, which can only be overcome by having a secondary light of less power than the primary, so arranged as to partially balance shadows cast by the primary. The same fault is present

in a more marked degree in the next system I purpose dealing with—viz., the electric light.

Illumination by electricity has been claiming a good deal of attention of late, causing at the same time somewhat unnecessary panic and confusion amongst all classes, photographers included. The praises bestowed on the new illuminant have been in the majority of cases trade quackery, and the insinuation that gas was to be superseded and obliterated for ever was simply a false representation made by company promoters to suit their own ends. Of all the systems of artificial lighting, I believe this, in its present condition, to be the most unsuitable for photographic purposes. The methods of production are too well known to all of you to need my taking up your time by descriptions. One system is now being tried in London with some success. I allude to the Van der Weyde; but whether it will stand the test of time remains to be seen. At present it is a novelty, and, as is usual in such cases, commands a certain amount of respect. This light is ordinarily utilised by its inventor for photographic purposes, to which he was the first to apply it. It is not, however, the production of the current, nor the means of converting into light, at which Mr. Van der Weyde has laboured, so much as the rendering of the light produced available as an illuminator, without wasting it, so to speak, and yet without throwing the rays directly upon the object to be illuminated. This he accomplishes by using the carbon rods as electrodes, placed vertically one over the other, the upper rod being $\frac{3}{8}$ -inch, and the lower $\frac{1}{4}$ -inch in diameter. These are placed near the mouth of a concave reflector; but none of the rays of light reach the spectator direct, as they are intersected by a disc of opal glass about 4 inches in diameter. The whole body of the light is gathered up in the reflector, and thrown out in a flood of pure white light. The current is produced by a Siemens's dynamo-electric machine giving continuous currents, and driven by a small Otto gas-engine. So far as I am aware, the Van der Weyde light has not yet been applied to purposes of general illumination.

The disadvantages of such a system are legion, and it is a mystery how any photographer could have the temerity to introduce such expensive apparatus into his studio. In the first place, motive power has to be supplied either in the form of gas or steam engine. The fumes from the former, and the vibrations of either, are most objectionable in the neighbourhood of a studio. A generating machine has next to be provided; and no matter what form be chosen, the cost is very heavy. A skilled mechanic would be needed to attend to the engine and machine, besides an electrical assistant to look after the lamp. The first outlay would be at least £200, and the sum required to meet the weekly cost would, I fear, be too large to allow of much margin for profit. Looking at it in this way, I do not think it at all probable that photography will benefit much from electricity, at least in its present condition. But, allowing that, by future invention and improvement, the cost of production and maintenance be lessened, there are other disadvantages to be overcome. The electric light is far from constant, either as regards luminosity or activity. I have now seen most of the methods in use, and they all flicker in a marked degree. The light is sometimes strong, and it suddenly becomes weak; at one time it is white, at another red; and, on more than one occasion, I have seen it, after changing from white to all the colours of the spectrum, resolve itself into darkness, and refuse to emit light at all. Variability in the composition of the carbon terminals accounts in a great measure for this; but, at present, all the aid that science can afford is not able to overcome these difficulties; and until the remedy is found, the electric light is useless as an aid to photography.

As regards the lime light, it can be dismissed in a few words, as I do not think it likely that we shall ever derive much benefit from its use. Its disadvantages, in a photographic sense, are almost as numerous as those connected with the electric light, and it has not anything like the power.

* Continued from p. 126.

I now come to the method which I believe to be the one of the future—viz., coal gas. The electric light scare, as it was called, although doing a great deal of harm, has not been unfruitful of good; it has taught us that all men are fallible, even American professors, and I hope it has shown Mr. (or rather, as he styles himself, Professor) Edison the folly of announcing to the world the success of an instrument before it was even invented, much less constructed. It has also put gas companies and gas engineers on their metal, and they have consequently shown that they can supply as powerful light as any electric system, provided the public care to pay for it. The rapid advance in the science of gas-lighting has been most marked during the past three months, and I firmly believe that it is gas and gas alone which will ultimately help us out of the difficulty into which we are plunged by the dark foggy days of winter. Gas as it is now burned in our houses lacks both power and activity in sufficient quantity to render it of use to the photographer, but it is in our power now to supply these defects, and from the results of some experiments now being conducted in Glasgow I believe that gas-light will soon be rendered both powerful and actinic enough to enable us to photograph by its aid. Amongst the various methods proposed for increasing the luminosity of the gas flame is that known as carburetted, which consists in adding to the gas before its combustion one or more of the hydro-carbons of which it has been deprived in the course of its purification, or which have been retained in the tarry products of coal distillation.

Here Dr. Drinkwater gave a description of the alcoh-carbon process and the carburetted process of Mr Macdougald, Dundee. These methods, he continued to say, although considerably increasing the luminosity of the gas at a small cost, are not to be compared with a new burner designed by Mr Sugg, the eminent London gas engineer. The burner is similar in construction to the Argand, only the gas is burned from a series of concentric rings, to each of which air is admitted. The light so produced is excessively brilliant, and under proper management is comparable with the Jablochhoff candle as at present used with the opal globe, which absorbs about 50 per cent. of the light. Here, then, in my belief, lies the future artificial illuminant of the photographer. What could be handier, what could be more cleanly? It would overcome one of the disadvantages of the luxograph which renders that instrument almost useless for children. The sudden flare up of the compound in the lantern would be certain to distract the attention of any child, if it did not frighten it altogether. By using the new burner we should have a steady, constant light, and with a little care one that would give good results, if not with wet plates, with any of the sensitive dry plates. In fact, for night work I think it probable that the dry plates will ultimately come into general use. From practical experience I know that they are extremely sensitive to ordinary gas light; how much more, then, would they be when that gas flame was rendered actinic by passing the rays through blue glass?

As regards the reflector to be used, I think the one at present attached to the luxograph could be greatly improved upon. I would construct it more of a parabolic form than spherical. As long as small flat mirrors are used, a true parabolic reflector cannot be made, and I therefore suggest a metallic mirror in one continuous piece, which would give all the above requirements.

Let me, before closing, sum up in a few words, the comparative disadvantages of the various systems to which I have alluded:—

1st. *Pyrotechnic Compounds*—(a) cost, (b) proneness to damp, (c) irritating fumes.

2nd. *Magnesium*—cost.

3rd. *Electricity*—(a) excessive cost, (b) difficulty of management, (c) want of uniformity in colour and intensity of light.

4th. *Luxograph*—loss of power by faulty construction of the reflector.

5th. *Gas*—at present I know of no disadvantage.

My task is finished, and if I have only succeeded in interesting you in the subject so that you may be persuaded to investigate and experiment for yourselves, I shall be satisfied. It is a subject of importance to us all, and I trust that my attempt to bring it before your notice this evening will be successful at least in eliciting the opinions of some of our members so that mutual benefit may accrue.

REMINISCENCES OF A PHOTOGRAPHIC VISIT TO GERMANY.

BY JOHN AMBLER.*

ON visiting a photographic establishment at Darmstadt one day, I was rather struck with the mode in which the prints were being washed. There was a wooden framework, about twelve feet by eight feet, on which was stretched, from end to end and from side to side, lengths of tape; the prints were laid on this network, and a copious supply of water showered upon them from a rose at the end of a length of india-rubber tubing. Of course this was done in the yard.

The village of Seeheim is one of those places you read about, but seldom see, consisting of a street proper and a few by-paths. From the castle there is a splendid view of the plain beyond. The ancient city of Worms is seen in the distance, and, as far as the eye can see, the Rhine winds its way along. Two miles or more from Seeheim is the Castle of Jugenheim, the residence of Prince Alexander, of Hesse, where H.R.H. the Duke of Edinburgh became engaged to the Grand Duchess Marie. I must say they chose a very charming spot for the delicate business, as the place abounds with lovely walks, and the air is perfumed with the sweet odour from the vineyards in the valley beneath. The inhabitants of the village of Seeheim were very polite. Each villager we met would greet us with a "Guten morgen!"—the men and boys raising their caps, and the females making a graceful curtsy. This got to be rather a nuisance, as I wore a Scotch cap, and it was not so convenient to be taking it off every few yards, especially if a dozen geese were endeavouring to bite your legs as you passed by. The people of note in the place appeared to be the pastor, schoolmaster, shoemaker, hotel keeper, and—I must not forget him—the antiquated joiner, whom we visited once or twice; but I cannot congratulate him on his sharpness, as we generally did the work, and paid him for the use of the tools. I could say much more about this village, but it would be hardly within the scope of this paper. I could mention the Lutheran church, where Princess Alice and family had their private pews, and where the female portion of the congregation sit downstairs and the males in the gallery.

After finishing our business at Seeheim, our next journey was to Potsdam and Berlin—a distance of about five hundred miles. The ancient town of Frankfort-on-the-Maine was our first stopping-place. The streets had a very busy appearance, it being the autumn fair. In shops which only occupied a few square yards of space, they seemed to be doing a splendid business. We had a hasty look round this important town—"the cradle of the Rothschild family." In some of the streets the top stories of the houses on each side were so close together that you could easily shake hands with your opposite neighbour through your bedroom window! The great drawback to the town is the abominable stenches which annoy you in many streets, as the drains flow along the streets uncovered. At the station a careless porter smashed one of our boxes, but nothing inside was broken—thanks to the felt packing.

* Continued from page 111.

After a sleepless ride we arrived at Potsdam about eight o'clock the next morning. We made our way to the palace of the Crown Prince, three miles from the station. Built of brick, with stone facings, the exterior of this royal residence has not a very imposing appearance, although of great dimensions; but the interior is most lavishly decorated. It was built by Frederick the Great, and so enormous was the expense, we were told, that he burnt the accounts, as he was afraid to look at them. The dome ceilings in many of the rooms are gilt-gold and silver, and the furniture likewise. There is a theatre in the palace decorated in a like costly manner. The walls and pillars of the banquetting-room are inlaid with rare stones and shells. We sat down to an excellent dinner in one of these beautiful rooms every day we were there. I well remember our first day there. I was about to enter the room where dinner was laid for Mr. McLachlan and myself, but the soldier on guard would not permit me to go in, charging his bayonet at me. I failed in my attempt to explain matters to him, so I brought her highness's valet to get me out of the difficulty.

We made the Hotel d'Angleterre at Berlin our headquarters. This hotel is close to the river which flows through Berlin, so that we can safely say we were "on the Spree" every night. Opposite was the Emperor's palace, and to the left the immense Free Museum, which takes the visitor a couple of days to see properly.

We went to Potsdam—a distance of twenty-three miles—almost daily for a month. By the kind permission of the Princess Royal we erected a wooden framework against the front of the palace (which, by the way, is a lofty building, and had the beneficial effect of subduing the top light). This framework was covered with cloths, forming a miniature studio, only it had to be taken down every night. The Crown Princess also offered us the use of a summer-house in her private garden for the purpose of a dark room, and into which Her Royal Highness and children would sometimes come to see the development of the negatives.

Although we were there a month you must not suppose we were photographing every day, for the time of Royalty was so filled up with Court appointments that sometimes we would have to wait a week or two before a sitting could be obtained. Singularly, it often happened that just at the time appointed it would commence to rain (this being the rainy month in Prussia), and then a tremendous gust of wind would come and blow the "studio" away! However, a sitting was obtained, Her Royal Highness being in evening dress, according to the design. Although we took four negatives at this sitting, none of them had the desired expression. Her Royal Highness then said that she and the Crown Prince would be receiving the King of Italy at palace in Berlin in a few days; after the reception she would be able to give a sitting. We accordingly took the apparatus to Berlin.

These photographs turned out unsuitable for the purpose of the group, the lighting at the Berlin palace being bad for portraiture. We could not tell how long it would be ere another sitting was obtained. Her Royal Highness was getting rather weary, so she asked Mr. McLachlan to search her album and find some photograph of herself which might do. As this was the last portrait required to complete the group, a satisfactory likeness must be obtained, or else it would mar the effect of the group, in which the portraits are so life-like. The Princess Royal, however, graciously granted another sitting at Potsdam palace, this being about the twentieth portrait taken; and, fortunately, it had just the very expression that was desired. Her Royal Highness was quite amused at Mr. McLachlan's determination, and told him that she had never seen such a determined man in her life; he reminded her of Robert Bruce and the spider.

Having already made this paper longer than I intended, I must close; but, before doing so, with your permission

I will show you a sketch of a useful lamp for the dark room which we saw at the premises of Messrs. Reichard and Lindner, photographers, Berlin. It is lighted with gas, the burner being a cylindrical one made of pot, but any burner will do. The square tin framework contains in two of its sides deep orange glass, on the third side a lighter yellow, and on the fourth side white frosted glass. The bottom and the top of the lamp are uncovered. When you develop the negative you have the two deep orange sides towards you, and when you want to examine for density you give the lamp a turn and bring the white frosted side towards you. The advantage is that you always have the same light by which to judge of the intensity of your negative. The backgrounds at this establishment are made of two widths of buff paper stretched horizontally on canvas.

They retouch their negatives, giving them, whilst damp, a coating of a solution of gum (one ounce of gum to ten ounces of water), and let them dry gradually. I don't think they varnish after. Of course by this method of preparing the negative for retouching you have an even "tooth;" but you must also have a fine touch, or you will easily scratch the film away.

I shall ever remember Herr Reichard, of this firm, for his kindness in showing us the sights of Berlin, not forgetting a visit to the spacious restaurant under the large Town Hall, where are daily sold eight thousand glasses of lager beer—a drink similar to our weak table beer.

When we had at last obtained the precious Royal negatives Herr Reichard bade us "Good bye!" at the Potsdam station at ten o'clock one night, as we were about to depart for England; but, before saying "Adieu!" I cannot forget the loving kiss and embrace which he gave, this being the custom among the men of Germany.

The next night, at eight o'clock, we were leaving Ostend in the mail steamer for Dover. It was a rough sail, which made me excessively ill during the seven hours it took to cross the Channel. Passing through London, Manchester was reached shortly after noon, and, not having had "forty winks" since leaving Berlin, I was thankful to get home.

PHOTOGRAPHY ON WOOD.

BY PROFESSOR J. HUSNIK.

I adopted the method of exposing gelatinized paper alone under a negative, and when the chrominn salt had been washed out, placing it on a plate of glass and laying on the ink with a very small glue roller. With this I succeeded completely; I obtained beautiful pictures, perfect in the half tones, which could be at once laid on the wood block, and be printed off at one impression. Gelatine paper can be easily prepared, and kept in stock, according to the process described in my book *Das Gesamtgebiet des Lichtdrucks*, by placing sheets of paper in a perfectly horizontal position, and coating them with a dilute solution of gelatine, and they need only be sensitized at the moment of use with a one per cent. solution of chromate; by this means the above described method is rendered thoroughly simple and practical, as well as being certain in its results. The wood block itself requires a very simple preparation; it must be rubbed down with whiting to which some adhesive substance has been added. This rubbing can be best effected by the ball of the hand. Gelatine paper can also be purchased from the dealers, and even my own photo-lithographic transfer paper will answer the purpose very well, provided that, before immersing it in the chromate solution, it be wiped over a few times with a damp sponge, and then rinsed well in clean water. This is done to remove any soluble matter from the surface. Afterwards the paper is dipped for some minutes in a one per cent. solution of chromate, then drained, and hung up to dry at an ordinary temperature. Sensitized in this way it remains good for the above named purpose for from three to five days.—*Scientific American*.

PORTRAITS BY ARTIFICIAL LIGHT.

A GOOD many photographers will sympathize with the remarks of our recent correspondent, Mr. Vincent Hatch,* when he expresses his conviction that photographers have already enough to contend with in their daily struggles, without introducing night business as a recognized element of the portraitist's business. But it should not be overlooked, on the other hand, that in many cases the daily struggles would be materially reduced by anything which increased the chance of income or adding to the facility for executing business. During a very large proportion of the time usually devoted in this country to achieving the day's work there is really no daylight in the photographer's estimate of that rare blessing. Hence, if artificial light can be made available, it can only be regarded as an unqualified boon. The photographer whose business and income, gained in the ordinary hours of daylight, are sufficient, will not need to trouble himself about artificial light, whilst insufficiently employed professional photographers and many amateurs will gladly avail themselves of the best facilities artificial light can offer them. We see no reason to fear that it will impose extended hours of labour on operators, who, if employed at all in night work, would, of course, be paid "over hours," and probably, as in most other crafts, at an increased rate of remuneration.

Be this as it may, there can be no doubt that the question of the best artificial light for portraiture is, at the present, interesting photographers in an unusual degree.

The electric light after the manner of Vanderweyde, and the system of Messrs. Alder and Clarke, have been tolerably fully described to photographers, and we need not, in noticing other methods, be supposed to enter into comparison with these patented methods. The plan suggested by the Rev. H. J. Palmer, and described in our pages a few weeks ago, is especially worthy of the attention of amateurs for the simplicity and efficiency of the mechanical contrivances. Mr. Harman, of Bromley, recently read an interesting paper before the South London Society on his experiences with some very similar appliances, and since the meeting we have had opportunity of personally inspecting the simple and ingenious contrivance. A square box, from thirty inches to three feet square, divided diagonally, gives a triangular chamber or recess, the two insides of which, lined with white paper, form reflectors collecting the rays of light, and throwing them on to a model placed a few feet distant. In this triangular chamber a very active pyrotechnic fire is burnt, and its

* These remarks were written before we had received the letter of "Operator" printed on another page; but they bear upon his letter as well as that of Mr. Hatch.—Ed.

glare and intensity are subdued and diffused by placing in front, forming the hypothenuse of the triangle, a sheet of tissue paper. Nothing could be simpler or more easily contrived, and, judging by results, it is exceedingly efficient. The pyrotechnic compound which Mr. Harman employs is, he finds, brighter and more actinic than the Bengal signal fire commonly used. He has been good enough to let us have the formula for the benefit of our readers. It consists of—

Nitrate of potash... ..	1½ pound
Flowers of sulphur	½ "
Sulphide of antimony	1 ounce
Finely powdered charcoal	½ "

An ounce of this is placed in the middle of some sand held in a metal dish, and fired by a taper put through a hole in the back of the chamber. In the top of the chamber is a hole, placed over which is an inverted flower pot, about six or eight inches in depth and diameter. From this a piece of pipe, or something of the kind improvised, may be made to carry off fumes into the open air. The ounce of the compound fired burns for about ten seconds, and gives a well-exposed negative at the cost of a halfpenny. Nothing could be well cheaper.

Mr. Harman boldly encountered two classes of difficulty at the same time. He was making his early experiments with the new rapid dry plates, and continued these in conjunction with the experiments in working with artificial light. Hence he was not perfectly satisfied with the negatives he exhibited at the South London meeting, which he described as "extremely bad." They were not that. They had the defects common in first attempts with gelatine: they were a little flat, chiefly from over-exposure. But the quality of lighting was very good. In order to get detail in the shadowed side of the face, Mr. Harman does not find a side screen reflector quite satisfactory, but finds it best to burn a piece of magnesium ribbon for a few seconds of the exposure, so as to give light to the shadowed side. The result is very satisfactory.

In very dull daylight, especially late in the day, a very few seconds of a good artificial light will be found to light up the head, giving pluck and brilliancy to the negative, which would otherwise be entirely wanting. This is a hint which the portraitist may find worth applying in cases of an imperatively desired portrait from a sitter who "cannot call again."

AN UNTRUSTWORTHY OPERATOR.

No one will, of course, attribute to a community the shortcomings of an individual, but all operators are concerned in discovering, if possible, and certainly disowning, the specimen described in the following letter from an old and esteemed correspondent. He says:—

"Two or three numbers back you inserted a humorous letter touching a correspondent's experience of 'operators.' Allow me to supplement his experience by some account of my own.

"I have been resident in the place I now date from nearly twenty-two years, and have had occasion to employ quite twenty assistants at various times. All (save one) turned out either *ungrateful* or *dishonest*; but my last experience, this very week, caps all.

"I employed a gentlemanly-looking person, evidently well up to his work, to photograph a school seven miles away. I trusted him with my wheeled dark chamber and a valuable lens. He did his work well, and sent me the negatives, which I printed from, and despatched, mounted, in a prepaid parcel; but one fortnight has elapsed, and I have never since seen my trap, my lens, or my money.

"My lawyer informs me I can prosecute for *breach of trust only* when I catch my trusted operator, who has, doubtless, a different name for every place he honours with a visit."

FOG, OVER-EXPOSURE, AND REVERSAL OF IMAGE.

BY C. BENNETT.

I HAVE been waiting for a little bright weather and for my spring plate-coating to experiment with a few rejected gelatine films. On the above subjects, any plates that may have accidentally been scratched or otherwise injured find thus an excellent opportunity to perform a service, and the result gained may interest some of your readers.

The difficulty of discerning from what cause a certain veil on a negative may arise is frequently great to those who only occasionally make use of these films, and also to those who, although often using them, have not personally made the emulsion or performed the whole of the operations.

I must be excused if I touch as a preliminary upon some parts of the subject that have already been canvassed, so that I may arrive, if possible, at a point still further. A negative, perhaps, is shown, having a certain amount of veil over it. What is the cause? Fog, or over-exposure? If from the former, it will arise from too much silver or too much light in working; if from too much silver, the veil is almost always uneven, and of a blue-black tint, and assumes more of a stain than anything else, differing greatly in that respect from the veil caused by light, which, although slight, or in whatever degree of intensity it may be, will still be of the same brown tone that a gelatine negative always is when developed with an alkali; so these two causes of fog may be identified with a considerable amount of certainty.

It may be assumed that it will not be difficult to detect whether, supposing the veil to be that of the brown tint, the fault is too much light, either connected with the exposure or with the other operations. If with the former, the negative will be excessively full of detail; and with the latter, if the exposure has been right, the detail will be obliterated, more or less.

It is obvious that gelatine films are more liable to these two faults than any other process, on account of their sensitiveness. Primarily, we have the difficulty of using a sufficiently moderate light to work by; and secondly, being used to other processes, we are apt not to realize the meagre exposures necessary.

There comes, then, the question of the effect of excessive action of light, whether in a small degree or in a larger, and it is to that end I have been using up a few plates.

We have indications in the other processes of reversal of image: the mere fact of a wet-bath plate being over-dense when not sufficiently exposed, and upon a further exposure being given the toning down of the high-lights showing the inclination to reversal; and I may not be wrong in saying that a bromized collodion dry plate film will show it even more readily, especially so from several remarks on the subject lately appearing in the weekly photographic magazines; and, again, to a greater degree do gelatine films exhibit that tendency, and yet hardly a tendency, because they do so out of absolutely necessity, the reversal being much more rapid and complete than with the others before named.

I have endeavoured to put my experiments in a visible form, as you will observe from the plates I enclose (the plates were put in a pressure frame and exposed, a card being drawn along at stated intervals).

On plate 1 there were five exposures.

A	1	second	weak	diffused	light
B	2	"	"	"	"
C	3	"	"	"	"
D	4	"	"	"	"
E	5	"	"	"	"

RESULT:

The negative gained density from A to B. Say B and C are the densest points, and equal to an under-

exposed sky. At D it is less dense, and at E it has toned down considerably, and equal to a sky in a fully-exposed harmonious negative. Plate 1, therefore, shows the loss in density after a given time.

PLATE 1.
Exposure.
1 2 3 4 5 seconds.

Increase in density. Decrease in density.

Plate 2 shows a result more advanced. B and C are still dense strips; but D has had a much longer exposure, and has toned down more than E in plate 1, and letter E on this plate has received a still longer exposure, and has toned down till its density is completely lost.

PLATE 2.
Exposure more prolonged.

Great loss in density.

Plate 3 exhibits a result still further advanced, the film having received at each letter after B a much longer exposure. B is the densest, but to letter C I have given a longer exposure than to E in plate 2, and it is almost colourless, and, in fact, when fixed would be bare glass, the developer not having influenced it, although B, which had only a tenth of its exposure, is quite dense.

PLATE 3.
Exposure much more prolonged.

Increasing in density in the second or positive reduction.

Now from this point C commences the reversal of the image—otherwise a positive—an equivalent to a transparency taken direct in the camera, because, as will be seen at the next draw of the card, viz., at letter D, the developer has brought out an image perfectly distinct; and, again, at the next draw—or, rather, a still longer exposure, viz., at E—the image comes up almost as dense as B, which is the densest point, the bare glass strip, viz., C, lying between the two.

These plates are not fixed, as they show best without—that is, viewed superficially; but were they fixed the strip C would represent positively bare glass, the midway point between the negative and positive reduction.

I also enclose a plate exposed in the camera, the shutter of the dark slide having been closed half-way after the negative image has been formed, to allow the positive to be formed, so that I get on one half of the plate the negative of the subject, and on the other half the transparency. It is so timed as just to show the negative over-exposed and fading away into the positive, which, on the other half, is faintly formed, and between which exposures there has been the bare glass stage spoken of at letter C, plate 3.

A delicate, lightly salted emulsion, containing, perhaps, ten grains of silver nitrate, appears to take the reversal far quicker than one of the heavily salted coarse and granular class; and especially where the silver is close upon its equivalent does this aptitude present itself.

If these remarks will assist gelatine workers to estimate preliminary stages of fog and over-exposure, I shall be glad, and especially if it should induce a discussion as to the chemical changes that take place, which I leave in other hands.

Although the negatives are not fixed, they will bear examination in ordinary diffused daylight.

NOTES ON BENNETT'S GELATINE EMULSION PROCESS.

BY W. WAINWRIGHT, JUN.*

IN January, 1878, a writer in the "Photographic Almanac" said of gelatine, "that it is equal in value to collodion, we think may be fairly predicated; that it is superior, is not yet evident." The same writer goes on to say with collodion "one may digest with excess of silver nitrate for days, and, with due knowledge of the treatment necessary at the after stages, may arrive at a pitch of sensitiveness which is scarcely attainable with gelatine without detriment to other necessary qualities."

Since the article referred to was written, a revolution has taken place with regard to gelatine. Instead of being equal in value to collodion, it is far superior to it in point of sensitiveness, cleanliness of working, exquisite detail, and quickness in developing. This change is owing to the free publication to the public by Mr. Bennett of the proper method of working gelatine—a result at which he arrived after much careful experiment. I do not claim for the negatives and prints I send round to-night that they are the best or the quickest that gelatine can produce. I show them as an amateur, and as examples of what any one may do by following strictly Mr. Bennett's formula.

There are many formulæ of various process published, but it is a question how many of them are workable by ordinary photographers.

As soon as Mr. Bennett had published his formula (and even before, as the process had been shown to many) the market was supplied with gelatine plates by various makers who had never before produced anything like them in rapidity or quality, nor can they now, except they follow his process.

Only the other day it was a matter of speculation whether gelatine plates could be used in the studio. Now many are using them to the entire exclusion of wet plates.

The process claims for itself, I think, the following special peculiarities, the combination of all of which leads to success:

- 1st. Lengthened emulsification.
- 2nd. Thorough washing, so that all the salts are eliminated.
- 3rd. The power of using a strong alkaline developer without any restraining bromide.
- 4th. The working in an extra non-actinic light.

The negatives I exhibit are all taken with a rapid rectilinear lens in sunlight. The exposure in April on trees is

15 seconds, and on all the others 7 to 10 seconds, with the exception of one which is nearly instantaneous. I have not myself gone in for very extra rapidity, which would entail emulsifying for from three to five days, but have contented myself for ordinary landscape work with an emulsification of 2½ days, and thorough washing, say 12 hours.

There is little doubt in my mind that owing to the liberality of Mr. Bennett a great impetus has been given to gelatine plates, and the trade and public will much benefit thereby. The formula I use is what Mr. Bennett has already published:

7 grains bromide ammonia
11 do silver.
90 do gelatine

I send round the prints and negatives together, so that members may be able to compare them together, and they will then see how vigorous and soft a print can be obtained from a comparatively weak negative.

PHOTOGRAPHY IN COLOURS.

BY M. K. VERSNAEYEN.

MANY people, latterly, have erroneously given to different systems of painting on photography the misplaced title "photography in colours." This was too much to say of the ingenious results, some of which were obtained by the transparency of the photographic image, some by other means. Nay, attempts were even made to make us believe that photographic proofs tinted by oil or water-colours were proofs obtained directly in colours. The only process which, up to the present time, has really deserved the name of "photography in colours" is that of M. Ducos du Hauron, but it is only still in infancy, its practice being very difficult, and the colours obtained not always being of the required tone. To arrive at the real colours of nature is no easy task, but we doubt not that M. Ducos du Hauron will, sooner or later, solve this difficult problem.

M. Germeil Bonnaud's process of photographing in colours—we use this term intentionally, because it is the only term strictly applicable—simply consists in causing the photographic action to operate directly on the colour. To this end M. Germeil Bonnaud has carefully sought the means of rendering a neutral colour sensitive, and at the same time insoluble, so that it might be able to resist the numerous baths necessary to the photographic process. When this process is used, all the operations remain the same as in the ordinary method, with this great advantage, that the impressions made by the silver salts on the coloured background give precisely the effect of the original model, and have not that hardness of tone that generally characterises a "retouched" photograph. The print comes out of the bath completely coloured. Thanks to the chemical agents and the sensitive paper used by M. Germeil Bonnaud, the colours and the photograph are henceforward indelibly united. But, in addition to the great artistic results, the material advantages of this discovery are very considerable. Firstly, the true harmony of colour is restored, whilst prints coloured by any of the old processes—photo-painting, as one might call them—are always monotonous and wanting in durability. By oil painting on the photograph, the employment of water-colours, or even of transparent media, the cost of production was immensely increased. And this was not all, because to obtain really artistic effects it was necessary to employ artists of such a degree of talent as is rarely found in country towns, where one does not find every day a Millais, a Dickinson, or a Nadar. Now the photographer can do it all himself. So much the better for those who are neither painters nor draughtsmen. It appears that the cost of the coloured photographs produced by the Germeil Bonnaud process is very little, if anything, more than the ordinary uncoloured ones. So we get at the price of an ordinary carte-de-visite a photograph in unchangeable and unfolding colours.

* Read before the Photographic Society of Great Britain.

PHOTO-TYPOGRAPHY.

BY CAPT. J. WATERHOUSE, B.SC.*

Photo-Blocks in Half-Tone.—Many attempts have been made from time to time to obtain surface blocks from photographs from nature and other shaded subjects, but with imperfect success. If this object could be successfully attained, it is easy to understand that it would be of immense value for book and newspaper illustration and many other purposes. There are, unfortunately, two grave difficulties to be overcome—one caused by the fact that to produce a successful printing block the surface of all the lines or dots which receive the ink must be very nearly on one uniform level, and therefore the moulding processes already described are inapplicable. The second and greater difficulty is to obtain a suitable grain to break up the continuous gradation of shade in the photograph.

M. Rodriguez, of Lisbon, has proposed an ingenious method by which promising results have been obtained. He makes a paste of sugar of milk, or some other substance in powder soluble in nitric acid, with a little oil of lavender and bitumen, and adds a sufficient quantity of it to a solution of bitumen in turpentine. The metal plate is thinly coated with this in the ordinary way, exposed to light, and developed with turpentine. The plate is then plunged into a bath of dilute nitric acid, which gradually penetrates the resinous coating, and dissolves the substance used for forming the grain, breaking up the preparation more or less according to the thickness of the bitumen, and thus reproduces the half-tints of the originals.

In many processes of collotype the gelatine film presents a very marked grain, which may be coarse or fine according to the composition employed. It is probable—though I have not tried it, nor, so far as I can recollect, seen it proposed—that blocks showing very fair half-tone could be obtained by taking a print from such a plate with a grain, transferring it to zinc, and then biting it in by a method similar to Gillot's already described. Very great care would have to be taken in the successive etchings to preserve the uniformity of surface and protect the finest tints from being bitten too much.

The prints in half-tone obtained by Mr. Dallas' process, known as "Dallastint," appear to have been produced by some such method. This, however, is only a conjecture on my part, because no details of the process have been published.

M. Rousselon has, I believe, obtained fair results by similar transfers from his engraved plates, and it is probable also that a transfer to zinc from one of the plates, prepared by the modification proposed by myself of Geynet's photo-engraving process, bitten-in in the same way, might also answer the purpose, though the grain is perhaps scarcely strong enough.

Details of several of the methods of photo-typography will be found in Motteroz's "Essai sur les Gravures Chimiques en Relief," and Scherer's "Lehrbuch der Chemigraphie."

Correspondence.

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

SIR,—I sincerely hope there are few photographers who are willing to adopt Mr. R. V. Harman's suggestion (in his paper read before the South London Photographic Society at their last meeting) relative to night-work in photography. There is no better advice than that contained in the old adage, "Make hay while the sun shines" (if I am not perpetrating too old a parody I would say, "Make photographs, &c.") That we get too little sunshine (especially during the winter seasons) by which to make

a sufficiency of photographs, to make photography a *perfect success* financially, I am sorry must be admitted.

If artificial lighting is introduced successfully into the studio, let it be to take the place of the sun when it should, but does not, shine, and not turn night into day. I would ask, Will the introduction of portraiture at night materially increase the business of a photographer? I think not.

With regard to Mr. Harman's city gent. who has a birthday in the family on the morrow, we will leave him with Mr. H. and our suburban brethren who know him best, just doubting if immediately after a good dinner and the usual wine is the best time to photograph gentlemen. At such time their good humour does not confine itself to facial expression, but is liable to break out in some witticism expressed in the middle of the exposure, when the joke, if ever so good, would be quite lost upon the operator. The British workman, we all know, is a very different subject, and I am afraid to think at what hour he would choose to have his portrait "took," provided the profession indulge him "after dark." Just fancy him ringing your bell about midnight, accompanied by several of his companions, for a group after leaving their favourite "pub." (where they generally manage to stay as long as the law will allow). I "guess" it would require an extra powerful light and a particularly *rapid* plate to get anything like a steady result. I am quite certain that all British workmen who wish to have their photographs taken, or who are worth photographing, will find time to have it done earlier in their dinner-hour, or on Saturday, when most of them have the after-part of the day at their own disposal. We have only to introduce night work into photography, and numbers will take advantage of the opportunity by being photographed as Mr. H. suggests; but if they cannot get what they want at night, depend upon it they will make time to be photographed during the day.

One thing to be feared is that some enterprising men will introduce portraiture by night, and compel others in the same district to do the same in self-defence, just as prices have been cut down in some places.

Let assistants look well to it, and oppose extra working hours all they can, and not have night turned into day by the introduction of artificial lighting. I do not wish to imply that assistants are overworked—indeed, I doubt if many have had sufficient to do to fill up their time for the last few months, and often, when there has been work to do, the light would not permit of its being done properly; then artificial light would be a boon. Night work as a regular thing should be opposed by all who respect their health or profession.—Yours, &c., OPERATOR.

P.S.—Mr. Harman in his paper gives a very lucid description of the apparatus he used to produce his pictures by artificial light: will he kindly publish the formula for the light he uses, as doubtless others besides myself will be glad to try it?

REVERSED NEGATIVES.

DEAR SIR,—I believe I may fairly claim to have been the first to suggest the method of reversing the collodion coated glass plate in the dark slide, with a view to the production of reversed negatives. This was as far back as 1862, when I was experimenting with my copper-plate process.

In 1863 I suggested the method to Mr. Francis Bedford, to enable him to take for me the view of Kenilworth Banqueting Hall, of which I subsequently engraved a plate by my process, and prints from which plate were presented by you to your subscribers on the 1st of January, 1864.

The method has only two disadvantages—arising, firstly, from the difficulty of obtaining glass free from bubbles and spots; and secondly, from the need of drying and polishing the bare side of the glass after removal from the bath—cloudy smears and drops of bath solution

* Continued from page 112.

being more fatal on that side than even hubbles in the glass, which are generally small, and may not come into an important part of the picture. However, with care in selecting the glass, wiping and drying the bare side, excellent reversed negatives can be obtained.

My object in now referring to the subject is to point out that as dry plates will soon supplant the bath process, the chief difficulty in obtaining reversed negatives by the above simple method is removed, and attention has to be given only to the use of good glass—it being easy to clean the bare side before exposure.

I must say I have always been surprised at the penny-wisdom which leads even some good photographers to use inferior glass for valuable negatives. I hold that if a negative was worth taking and keeping, it should be on patent plate. Especially is this now important, when I believe photo-mechanical processes in permanent printing inks will supersede at no distant date (except for very large work in small numbers) both silver and carbogelatine printing.—Yours truly, DUNCAN C. DALLAS.

362, Gray's Inn Road, March 15th.

CLEAN PLATES.

DEAR SIR,—The omission of a word in my little article on "Clean Plates" in your last impression has made all the difference. The beginning of the fourth paragraph should be "I may, perhaps, mention that I never use a substratum *except* for dry plates, &c."

Your answer to G. Taylor in the same number has reminded me of a circumstance which occurred a few days since that may serve as a caution to some of your readers.

I found, after varnishing a 12 by 10 negative, that it was rather too dense for the purpose required, so I decided to remove the varnish and reduce the intensity. I proceeded as usual to lay the negative in a dish, and covered it with methylated alcohol, opening a fresh gallon jar for the purpose. All went well for a minute or two, but on lifting up the negative to ascertain if the varnish was removed, I found it was, *and the picture with it*. The reason, of course, was that the methylated alcohol was stronger than that used for the collodion.

Luckily, the object photographed was still in my possession; the damage, therefore, was in my case easily repaired by taking another picture.

In future, however, when I have anything of the kind to do, I shall, if possible, try the effect on a worthless negative taken with the same sample of collodion as the one from which I wish to remove the varnish.—Yours truly,

F. A. BRIDGE.

Norfolk Road, Dalston, March 1st.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The usual monthly meeting was held in the Water Colour Gallery, Mr. J. GLAISHER, F.R.S., in the chair.

The minutes of a former meeting were read and confirmed, and the following gentlemen duly halloted for and elected:—Messrs. G. L. Addenbrooke, A. Cowan, W. H. Wheeler, and Captain G. S. Clarke, R.E.,

CAPTAIN ABNEY, F.R.S., then read a paper on "Coloured Glass Suitable for the Developing Room, and on the Employment of Sulphate of Quinine as a Substitute."

The discussion on this paper was postponed.

Mr. C. BENNETT read a paper on the "Gelatine Emulsion Process" (see p. 133).

Mr. W. WAINWRIGHT, Jun., exhibited some negatives produced by Mr. Bennett's process, and read a note on the subject (see page 140).

A number of prints from gelatine negatives were shown by Mr. Cobb, and by Mr. Hemery a print from a gelatine negative taken in four seconds.

Mr. BERKELEY exhibited a failure he had met with in plates which had been prepared with excess of silver and gelatine washed, and after keeping for a few weeks, had turned red previous to development. The plate shown had been kept in a plate box, and he did not think any free silver was present, as the washing waters showed none on testing.

CAPTAIN ABNEY said that free silver combined with gelatine and formed a definite compound. This compound could not be got rid of by washing.

Mr. BERKELEY, replying to Colonel Wortley, said he used Nelson's opaque gelatine; the usual kind sold at 6d. a packet.

Colonel WORTLEY found it impossible to use opaque gelatine. Nelson's No. 1 was the best.

Mr. BENNETT remarked that opaque gelatine gave the red fog complained of by Mr. Berkeley.

Mr. SEBASTIAN DAVIS asked Mr. Bennett what was the effect produced by allowing the emulsion to remain a long time at a high temperature.

Mr. BENNETT said the emulsion became creamy up to about twelve hours' keeping; after that, although it rapidly became quicker, it did not show any more creaminess, because as much of the silver had been taken up as was possible. There was, he thought, an organic decomposition set up as well as the decomposition of salts.

Mr. BENNETT, in answer to a question, said he had already stated he preferred Nelson's No. 1 gelatine. With reference to the fogged plate just exhibited, he might say that there were very few samples of opaque gelatine which would not show a red fog. He presumed that the higher temperature at which the opaque gelatine was cleared had something to do with it. He did not find opaque gelatine, when emulsified for several days, answer at all.

Mr. MAWDSLEY had worked Mr. Bennett's process for some time, and could confirm all that had been said in its favour. He had been a maker of dry plates for many years, but had never found anything until the publication of Mr. Bennett's method which combined so much sensitiveness with, at the same time, such good quality.

Mr. COBB had used gelatine plates commercially for nearly four months, to the entire exclusion of the nitrate bath, and could fully endorse what had been said of their rapidity and quality.

Capt. ABNEY observed that he did not like to see old friends thrown overboard, and he must confess he had seen nothing in the specimens of gelatine work exhibited that night which could not have been produced by collodion. In the paper he read before the Society last meeting, he stated his views on the gelatine process, and undoubtedly it was an admirable process, but there was still much to be desired so far as control of development was concerned. With respect to their sensitiveness, it might be interesting to inquire as to what the increase in this direction was due. In the winter light, as any one who studied the actinometer knew, there was a great absence of blue rays, and it was these blue rays on which the sensitiveness of the wet process depended; but of course, if they were not present, they could not be used. Now with the gelatine plates the yellow rays were of actinic use, and hence the value of these plates in winter; but when the summer came, he did not think there would be that remarkable difference between the two processes which some anticipated. So far as the introduction of dry plates into studio work was concerned, he believed that Col. Wortley five or six years ago made a practice of taking large portraits with collodio-emulsion. Collodion had been a very good friend to the photographer, and he (Capt. Abney) did not like to see it hurriedly cast aside for a new love. The photographer knew what collodion was made of—or at least he ought to do so—but he could not be so sure about gelatine. It was almost impossible to get two samples of the latter alike, and it was necessary to modify the manipulation accordingly. He need only refer to the experiments made by Dr. Eder to show what an enormous number of varieties of gelatine there were, and his own experience was that you could not get two samples to produce exactly the same results. Now with collodion it was an easy matter to know all about it, and a picture could be so modified in the development as practically to produce any results wished for. He confessed he had not been able to do this with gelatine, and would be glad to have a lesson from anyone who knew how.

Mr. BENNETT: It is one of the faults of the collodion process that it has to be treated locally. Now, with gelatine you do not it is perfect in itself.

Captain ABNEY: Mr. Bennett's process is undoubtedly very perfect, but it leaves nothing to the artist in regard to modifications of development.

Mr. FRANCIS BEDFORD felt the force of Captain Abney's remarks in regard to the greater control of development in the collodion process. It was quite possible by judicious development to get an artistic effect in the negative which did not exist in the object. An atmosphere could be given, and he had seen by this means a ray of light brought against the figure which was not in the original. It was also a great advantage to be able to work in comparative light, and be able to see what one was doing. He would suggest that it would be advisable to work the two processes side by side rather than for the exponents of one process to discourage those of the other.

Colonel WORTLEY thought the meeting ought not to wander into a discussion as to which was the best process. It was certainly due to Mr. Bennett to say that his process was as far in advance of any process hitherto published as a Great Northern express engine was in advance of Stephenson's Rocket. He (Colonel Wortley) had done good work with collodion bromide, but, so far as gelatine was concerned, Mr. Bennett's process was greatly superior to any other. Mr. Burgess used to send out very good gelatine plates, and no one produced any better ones until Mr. Bennett came forward. It was only due to Mr. Bennett to say this.

The PRESIDENT suggested that the discussion be adjourned until the next meeting, which he begged to remind the members would take place on the first, and not the second Tuesday in April. In alluding to Mr. Bennett, the President referred to his liberality in giving his process openly to the world, instead of keeping it to himself, as he might easily have done, and in all probability realised handsomely by it.

After votes of thanks to Captain Abney, Mr. Bennett, and Mr. Wainwright for their papers, the discussion was adjourned.

Mr. YORK exhibited an instantaneous shutter band on Mr. Cadett's principle. The feature of the shutter was that it opened inside the camera at the back of the lens, and thus did away with any risk of startling a child, which those in front of the lens were apt to do. Mr. York observed that the objections to shutters inside the camera was that they raised dust, but his answer to that was that there should be no dust to raise.

A specimen of enamelling by a new method sent by Mr. David Gay, of Hanley, was handed round. After which,

Mr. HOWARD GRUBB exhibited two stereoscopes of a novel construction. The first was intended for transparencies, and consisted of two lenses and two prisms so arranged as to bring the right eye only on the right-hand picture, and the left eye on the left-hand picture. The arrangement of the lenses and prisms also superimposed one picture on the other, and thus a perfect stereoscopic effect was produced, much more pleasant to the eye, and with less fatigue to the viewer than in the ordinary method. The second stereoscope was intended to exhibit pictures of a larger size. Mr. Grubb mentioned that he had lately shown a book written by a monk, and published at Antwerp in 1513, in which the whole principle of binocular vision was laid down and illustrated by diagrams.

After some conversation on an illustration of the tenacity with which gelatine stuck to glass, shown by Mr. Sawyer,

The PRESIDENT called attention to the fact that March 31st was the last day for sending in competitions for the Paget prize, and announced that the Presentation Prints, which could be had mounted or unmounted as the members desired, were in the room ready for distributing.

The meeting then adjourned.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The second popular evening of this Society was held in Queen Street Hall, on the evening of Wednesday, the 12th ult., when a large attendance of members and their friends assembled to see a collection of transparencies produced from the work of members during the past year.

The entertainment was of a most enjoyable character, the audience continually giving marks of approbation. The pictures illustrated the most diverse localities, including picturesque Scottish scenery, architectural interiors (chiefly Continental cathedrals), and views illustrative of India and Indian life. The whole of the slides were new, expressly prepared for that evening, many of them possessing peculiar merit.

The individual task of the members was shown quite a

much in the colour and treatment of the transparencies, as on the original selection of the subject, many of the tints being peculiarly appropriate to the special requirements of the pictures, browns and warm purple predominating.

Descriptive notes were delivered by Mr. W. H. Davies, honorary lecturer to the Society. The lantern was splendidly managed by Mr. Yerbury. Dr. Hunter proposed a vote of thanks to Mr. Davies, which was heartily accorded.

PHOTOGRAPHIC SOCIETY OF VIENNA.

At the meeting of the Society on the 31st January last, the chair was occupied by the President, Dr. E. HORNIG, for the first time after more than a twelvemonth's absence at Paris, where he has been detained by his duties as chief of the Austrian Commission at the late International Exhibition.

The attention of the Society was drawn to the numerous and valuable collection of objects sent from various quarters for exhibition at the meeting. Prominent among these was the reproduction of a landscape painting in colours by colotype, accompanied by the plates used in printing it, from Herr Albert, of Munich. It is understood that Herr Albert has recently entered into an agreement with M. Ducos du Hauron to work in alliance with him.

Deserving special notice were also a set of twelve cabinet pictures from Herr Salomon, photographer by appointment at Dessau, and a beautiful collection of sixteen selected photographs by Messrs. Schober and Baechmann, of Carlsruhe, reproductions of drawings by the old German masters. Under the title of "Album for Sportsmen and Naturalists," Messrs. Eckert and Muller, of Prague, had submitted a set of twenty-seven photographs of stuffed animals with suitable surroundings; these were greatly approved as drawing copies.

Herr F. BOPP sent some stereoscopic pictures on glass of injected anatomical preparations, and attention was drawn to the difficulties under which they had been produced, both on account of the colour of the originals, as well as of the position in which the reproductions were taken. Because of the corrosive nature of the injected fluid the preparations would have fallen to pieces on the least shaking; they were, therefore, obliged to be laid in a horizontal position, and the camera was placed over them and directed vertically downwards.

Dr. HORNIG submitted to the meeting a short report on the working and finances of the Society during the past year.

In reply to an address from Count V. WIMPFEN, eulogising his services at the Paris Exhibition, and gratefully acknowledging the care with which he had watched over the interests of all the Austrian exhibitors, and more especially of those who were members of the Society,

Dr. HORNIG returned thanks for the honour that had been conferred on him, and assured the meeting he would continue, in whatever position he was placed, to work for the benefit and prosperity of the Society.

Herr SILAS exhibited an electrical shutter of his own devising for uncovering the objective. The same is placed inside the camera, and can therefore be worked without the person whose photograph is being taken observing the action. The arrangement consists of a couple of doors moving on hinges at the back of the slide. When focussing, these are kept open by a pin, and are closed by breaking the electrical circuit. An insulated wire permits the operator to stand at any distance from the instrument, and ends in a spring, on pressing which contact is made and the doors fly open.

Herr OSCAR KRAMER introduced the subject of photography in the High Alps. In discussing the respective advantages of the wet and dry processes for this purpose, he expressed an opinion that before long the latter only could be employed in mountain work. From some photographs of subjects in the neighbourhood of the Gross Glockner taken in the year 1863, and comparing them with the same views taken in 1875 and 1878, he took occasion to enlarge on the services that photography could render to natural science, and in this case more especially to physical geology, by proving the advance or contraction of the glaciers. The speaker passed round at the meeting a number of views of Alpine scenery taken by Herr J. Beck, of Strasburg, from the summits of many of the loftiest mountains in Switzerland—Monte Rica, the Mouch, the Jungfrau—at heights varying from 2,000 to 4,635 metres. These had all been taken on dry plates, and, notwithstanding the great difficulty under which the work had been executed, surpassed anything of the kind that had as yet been seen. True to the principle of division of labour, Herr Beck had himself

exposed the plates, leaving the rest of the manipulations to be executed by a professional photographer in Berne. His success seems to prove that good dry plates, any prejudice to the contrary notwithstanding, are exceedingly durable, and are able to endure the extremes both of heat and cold.

Talk in the Studio.

PHOTOGRAPHS FOR SEASONS.—We are favoured by Mr. Warwick Brooks, of Manchester, with some very charming examples of what he terms the "St. Valentine Photograph." The examples sent are vignetted portraits of some pretty girls with an exceedingly pretty outourage printed-in. It consists, apparently, of photographs of some embossed laco paper, forming a border round the vignette, ferns, flowers, and ribbons being tastefully added to give completeness to the designs. As Mr. Brooks suggests, such photographs for various reasons might be produced during dull seasons, and at once advance the art and benefit the photographer.

PRESENTATION PRINT.—The Photographic Society of Great Britain has decided to present to members a print of one of the photographs exhibited at the last Exhibition. The print selected is one of Betws-y-Coed, exhibited by the School of Military Engineering, Chatham, which gained the medal for the best single landscape. It is printed from a reproduced negative by the Autotype Company, by their Collotype process, and is cut rectangular, although the original was exhibited in an oval mount. Any member wishing to obtain his copy mounted, can do so by calling for it at the Autotype Company, 36, Rathbone Place, after giving them four days' warning before doing so. After April 15th the Presentation Copy will be forwarded, unmounted, to all members who have not called for it mounted.

NEW CARBON PROCESS FOR PRODUCING ENLARGEMENTS IN THE SOLAR CAMERA.—Dr. Monckhoven, in the "Bulletin of the Association Belge de Photographie," describes a process for making carbon enlargements in the solar camera. A solution of wax in benzine is prepared and rubbed on the surface of the glass with a piece of flannel. The plate is then coated with solution of gum-dammar, and is kept in water for half an hour. It is then taken out and placed flat on a table. A piece of carbon tissue is squeegeed on to the surface, and is allowed to dry in the dark, or else the surface is coated with coloured and bichromated gelatine. The gelatine surface is exposed to the image formed in the solar camera through the glass plate, the exposure being regulated by an actinometer. The plate is then plunged for a quarter of an hour into warm water of 30° C. (86° Fahr.), afterwards in water heated to 60° C. (150° Fahr.); the paper detaches itself, and the image is developed as usual. After it has been made insoluble with alum it is allowed to dry, and white gelatinized paper is squeegeed on to it. When again dry, the picture is detached. If the transfer paper be of a very glossy surface the picture preserves its polish even when mounted on cardboard, whilst if the gelatinized paper be "mat," it appears like an ordinary single transfer print. The author finishes the description of the process by noting the following novelties in the process through the exposure taking place through the glass plate:—1st. Through never detaching the tissue, reticulations of the image and spontaneous insolubility of the gelatine are avoided. 2nd. The paper remains perfectly flat during a long exposure. 3rd. There is no risk of bubbles or want of adhesion to the temporary support, which often occurs in the double transfer process. And 4thly. The prints are not reversed, and are exquisitely sharp.—*Photographic Journal.*

ELECTRIC LIGHT IN THE BRITISH MUSEUM.—Some months ago an article strongly recommended the use of the Electric Light in the reading room of the British Museum. The experiment has recently been made, and, we learn, with success. The *Times* says: "The experiments with the electric light recently made in the reading-room of the British Museum have satisfied the trustees of its applicability for the purposes of the room as far as the amount and distribution of light are concerned, although the full number of lamps was not employed. On three occasions the light was turned on at dusk, in order to enable readers to continue their studies without interruption for another hour. As far as could be ascertained, they were enabled to work by it without difficulty, even at the tables where the light was weakest. The experiments were made gratuitously by the Société Générale d'Electricité, who use the Jablochkoff candles. They are discontinued for the present, but a further

trial of the light will probably be made some months hence, with the view to utilize it on dark days and for extending the hours for using the reading-room in the winter."

FIXING THE EYE IN PORTRAITURE.—The *Danbury News* says:—"English photographers avoid the strain on the sitter's eyes, which usually results in a ghastly stare, by having a clock-face as the point to which they are directed, the eyes being allowed to travel slowly from the figure XII all round. The rotary movement of the eye ball in adapting itself, step by step, to the figures upon so small a circle at such a distance is so excessively fine as to cause no interference with the photographic process. The eyes are excellently well defined, even to the iris, and the pictures have a marked superiority over those previously taken in the manner in which the details of the eyes are reproduced. The sitters have expressed themselves as not having had any strain upon their eyes."

THE HECTOGRAPH.—Herr Levitus, of Vienna, lately exhibited an arrangement called a "hectograph" for multiplying writing, which, though not directly connected with photography, may prove interesting. The hectograph consists of a flat sheet iron box filled with a gluey mass, upon which, after moistening and drying it several times, a sheet of paper, written upon with a specially prepared ink, is placed, and lightly rubbed with the hand. When the paper is raised the writing is found to be transferred reversed to the film of glue, and from that film, by simply placing pieces of dry paper upon it and rubbing them, some fifty impressions of the writing can be taken in a short time. The negative impression can easily be removed from the film by washing with warm water, and the latter can be used over and over again for a long time.

To Correspondents.

TIVOLI.—On another page we give the formula for Mr. Harman's pyrotechnic fire. It is probable that any druggist will prepare it for you. We do not know where Mr. Harman purchases his; but unless you were in the same neighbourhood, it might be of no use to you to know.

PYRO.—We believe the remuneration of an apprentice in photography is invariably the subject of specific agreement, and that no general rule exists. In one case which came under our knowledge, the apprentice was bound for three years, receiving nothing for the first year, five shillings weekly for the second year, and ten shillings weekly during the third year.

M. M.—So far as we know, the use of any kind of artificial light has not been patented for photographic purposes, only the appliances for using various lights. Mr. Vanderweyde has not patented the use of the electric light, nor have Messrs. Alder and Clarke patented the use of any special pyrotechnic compound for photographic purposes. They have each patented certain appliances for producing portraits by artificial light. Mr. Harman's, described last week, is quite free for you to use, and that of Mr. Palmer described a few weeks ago. Your lament to the effect that every valuable novelty in photography is locked up by patent restrictions is really not based on facts; and if it were so, you would scarcely complain, if you were engaged in gold digging, that every one who found a big nugget kept it for himself, instead of dividing it among his fellow diggers. Be energetic and hopeful, and avoid looking on the dark side of things.

G. L. M.—There are very rapid collodion emulsion processes, but, so far as we know, none so rapid as the gelatine processes. Some years ago we reported trials of dry plates, by Colonel Wortley, against the most rapid wet plates then known, and the dry plates of Colonel Wortley were victor.

COLLOTYPE.—The autotype process, at the present time exciting considerable attention in America, is, we understand, a photocollytype process by M. Obernetter. It is stated to be a great improvement on previous processes. Some results we have seen are exceedingly good. So far as we know, the details of the process have not been published.

TRY AGAIN.—In our experience the best method of securing a warm tone in collodion positive images for transfers or transparencies consists in, besides having all the chemicals in good working condition, giving a full exposure and rapid development, using pyro and acetic acid. If the exposure be short, and the development has to be pushed a little, a black tone is generally the result. 2. No. Iron generally gives grey tones.

LITTLE PHOTO.—If our correspondent will furnish us with his present address, or if he will call at 59, Vincent Square, Westminster, he may hear of something to his advantage.

AMSTERDAM.—If Mr. Haakman, Secretary of the Photographic Society in Amsterdam, will forward the medal awarded to Mr. A. M. Penn, it shall be duly forwarded to the proper quarter.

Several correspondents in our next.

The Photographic News, March 28, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE PAGET COMPETITION—THE PRESENTATION PRINT OF THE PHOTOGRAPHIC SOCIETY—PHOTOGRAPHY AND THE DRAMA.

The Paget Competition.—The last day for forwarding dry plates for the Paget competition is fixed for Monday next. We have little need to remind our readers, for notices to that effect have been broadly circulated. "The negatives and dry plates, in sealed packages," are to be addressed to Mr. Sebastian Davis, the honorary secretary of the award committee, at the Society's place of meeting, 5A, Pall Mall East; and no intending competitor will be permitted to take part in the contest if he does not fulfil these conditions. The award committee have no slight task before them, even if the competitors do their utmost to assist by strictly complying with regulations, for since gelatino-bromide plates have come to the fore, there can be little doubt that the number of competitors will be increased. We trust the award committee will take a thoroughly practical view of the matter, and give us a process which shall be successful under something less than scientific conditions. There is no need to fear that the matter will not be thoroughly tested by the men chosen to act as jury, for they are one and all thoroughly well acquainted with the subject they have to deal with. It will be remembered that ten, two or three years ago, the French Government and the Photographic Society of France organized a competition of the same kind at Paris, and for pretty nearly the same object, there were but two competitors, or, as it turned out, only one, who had complied strictly with the regulations. This was M. Alfred Chardon; but the process he submitted was so satisfactory that he was at once adjudged the winner. There can be no doubt that M. Chardon's process—a collodion emulsion method—is a very good one, as M. Davanne, the president of the jury, was able to testify by actual trial; but it does not equal in sensitiveness the gelatine emulsion processes of the present day. In the case of M. Chardon the prize was but 500 francs, or £20, but the *Academie* subsequently conferred some honorary distinction. Captain Paget's prize, on the other hand, is of the value of £50, and therefore well worth fighting for. We only hope that the competition will not turn out simply a "walk over" as in Paris, but that there will be some good and new processes forthcoming. Of course, skill and acquaintance with materials are always necessary to secure good results, but we hope that the chosen method will be one that can be worked by any one promising these qualifications. It is too often the fault of dry processes that they yield only first-rate pictures in the hands of those who have elaborated them and worked them out in detail, and who are acquainted, therefore, with the behaviour of the materials at various stages. Given into the hands of another equally good photographer, the process is less successful, and the consequence is that we see many gentlemen working many processes, each giving satisfactory results, although differing in their details. What, of course, is generally wanted, is a good and simple process, that depends not so much upon the intimate acquaintance of the operator, but which furnishes equally good results in the hands of the general body of photographers. If the award committee can pick us out such a process from those submitted, we, for our own sakes, shall be deeply grateful.

The Presentation Print of the Photographic Society.—It is pleasant to find that the Photographic Society has once more gone back to its early custom of distributing Presentation Prints to its members. A very large proportion of the latter are unable to attend its meetings, by reason of their residing at a distance, and many more are amateurs who would especially prize a print such as the Society was formerly in the habit of presenting to all members. We

trust, now that the custom has been revived, it should not be lightly abandoned. There should be no reason why the Committee which awards the medals at every Annual Exhibition should not also take upon itself the duty of selecting a Presentation Print. It would be very strange if the lucky photographer whose work was selected would not feel honoured by the distinction, and there is little doubt an arrangement of some kind could be entered into, alike satisfactory to him as to the members. On the present occasion, as our readers are no doubt aware, the print selected was one of the finest in last year's Exhibition, and gained a landscape medal. It was exhibited by the School of Military Engineering at Chatham, until lately under the charge of Captain Abney, and now no less ably directed by Lieut. Darwin, the Present Honorary Secretary of the Society. The impression is to be printed by the Collotype process, from a negative reproduced by the Autotype Company, and, although the experiment is a bold one, we believe that the beauties of the picture will not suffer. From the circumstance that the scene is Bettws-y-Coed, in North Wales, and that no Royal Engineers are to be found stationed near that sylvan retreat, we may well infer that the picture was secured during the holiday of one member or other of the School in question, while rumour goes so far as to say that it is the director himself, and no other, who is the author of the charming negative. How far this is true we have no means of knowing, since the catalogue only tells us that the School was the exhibitor, while we know that to the School was the medal awarded. One thing is clear, that we may fairly congratulate Mr. Darwin upon his direction of a body which can produce so fine a picture as the Presentation Print of the Photographic Society for 1879.

Photography and the Drama.—It seems strange that playwrights should always make a muddle of it when they have to do with photography. In a drama that has some very sound and striking points about it, recently produced at the Grecian, the same absurdity is committed as that in the *Octoroon*. In Dion Boucicault's play, it may be remembered, we have the circumstance of a photographic plate revealing a picture after it has been treated in a very bad way. A man is sitting down having his portrait taken, when he is suddenly murdered. The instrument is open during the whole of the operation of killing, and hardly is the affair ended than the boy entrusted with the capping of the lens returns. The latter has been instructed to open the camera, and then run to a tree and back again, before capping once more. In the meantime, as we have said, the deplorable incident in question has taken place. The boy closes the lens, and then turns round to see the sitter has been murdered. He knows nothing of cameras and lenses, and, in his ignorance, imagines the apparatus must have done the mischief, whereupon he proceeds to knock the camera to pieces. Despite this ill-treatment, however, the plate is subsequently recovered, and behold, when it is examined, there is a picture upon it of one man murdering another; proof enough to secure the conviction of the malefactor. We believe there is nothing said about developing the plate or fixing it, but these are, after all, small matters. In the *Last Stroke of Midnight*, at the Grecian Theatre, there is an incident much resembling that in the *Octoroon*. In the last act the hero and his bride are about to be made happy, when the villain of the piece, one Gonzales, enters and charges the young man with the murder of a comrade. The hero appears unable to prove his innocence, and there is a probability of the accused being dragged away a prisoner. In this dire strait, a photograph is fortunately forthcoming, and this proves to be a picture of the man in the act of being murdered. There is the murderer cruelly stabbing his victim, and the murderer is shown to be no other than Gonzales himself. It is a pity our dramatists cannot employ photography in their works without going the length of such improbabilities.

COLOURED GLASS SUITABLE FOR DEVELOPING ROOM.—EMPLOYMENT OF SULPHATE OF QUININE AS A SUBSTITUTE.

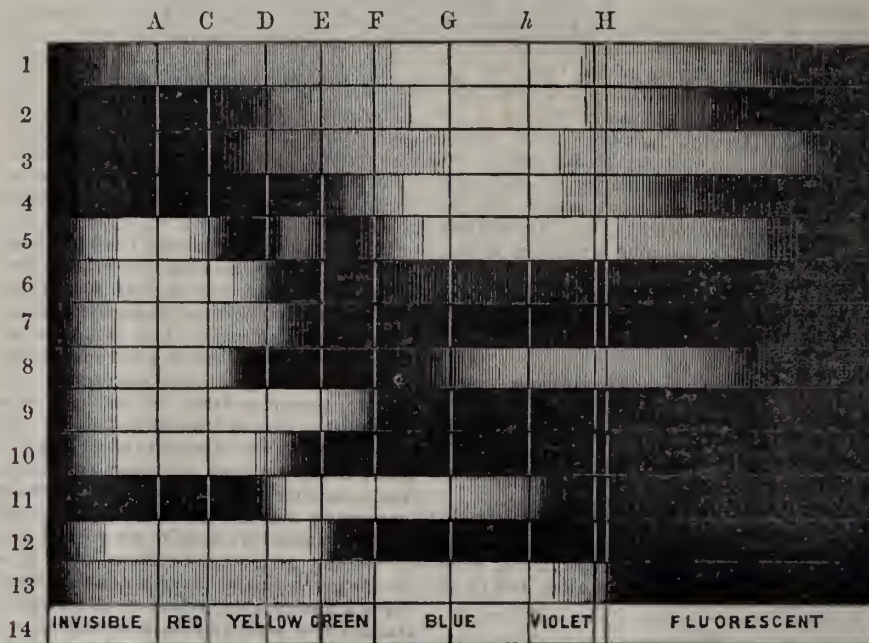

BY CAPTAIN ABNEY, R.E., F.R.S.*

THERE seems to be a great deal of mystery enveloping the subject of the light which is admissible into the dark room, and I have deemed it advisable, as far as possible, to clear up some of the hallucinations which exist.

In choosing a glass for the dark room it is above all things necessary to know what silver compound is to be used in it, as on that point rests the choice to be made. The accompanying photographs will aid the photographer in unravelling this knotty point. They were taken in the following manner:—An ordinary spectroscope adapted to photography was employed, and close in front of the slit a card cut in this manner was placed—

the top opening being first of all in front of the top of the

1, Special collodio-bromide; 2, gelatine bromide; 3, collodio-bromide; 4, bromo-iodide; 5, cobalt glass; 6, ruby glass; 7, chrysoidine; 8, magenta; 9, flashed orange; 10, stained red glass; 11, bottle-green glass; 12, aurine; 13, quinine.

Now a glance at the diagram will show that for the bromide there is no absolutely safe single glass to employ by which to develop. If the light be strong, the ruby glass (Fig. 6) lets through the red a little yellow, green, and blue; whilst the stained red (Fig. 10) lets through the orange, to which this salt of silver is sensitive. How, then, can we secure immunity from the reducing action of light? By combining the stained red and the ruby together. This admits plenty of light; but a safer combination than these is a combination of cobalt glass (Fig. 5) and stained red glass. In the photograph is shown the absorption spectrum of cobalt glass. It will be seen that it cuts off the green and yellow entirely, but allows one deep band of red to pass, and a faint band in the yellow-green. The

slit. When any glass was to be tested it was held in front of the cardboard, the plate next placed in the camera, and sunlight reflected on to as much of the slit as was visible. The white light was thus filtered, as it were, through the glass, and the colours absorbed found no means of access to the sensitive plate. The plate was coated with the blue silver bromide which I prepare by my method, and which is sensitive to all radiations of the spectrum. The sunlight is then reflected away from the instrument, the lower aperture in the card brought in the front of the slit, leaving the bottom half uncovered, and another piece of glass or absorbing medium placed in front. The exposure again takes place; and we have the absorption spectra of two glasses impressed one below the other. The fixed lines of the solar spectrum show exactly where the absorption takes place.

The first four photographs show the rays to which the different kinds of films are sensitive. The next eight photographs show the absorption spectra of different coloured media. From these we shall be able to form an opinion of the respective merits of the different glasses. You will see that there is no action on the plate below the green where bromide-iodide is used, but that it extends to C, where the bromide is used.

stained red glass will cut off the blue and the yellow-green as shown in the photograph (Fig. 6). Therefore all the light that will pass is contained in that narrow band of red light which can traverse both the stained red and the cobalt blue glasses. When using coloured glass, the stained red and the ruby are, however, the best combination. Some of the other photographs show that other modes can be employed to obtain non-actinic light. Here we have photographs of the light passing through a collodion film dyed with magenta (Fig. 8), with aurine (Fig. 12), and chrysoidine (Fig. 7). It will be noticed that the combination of magenta with either of the other two is as effective as the cobalt and stained red glass. To the photographer who has dyes at his disposal this is a boon, since by coating one side of an ordinary sheet of glass with one dye, and the other with one of the others, he may procure a light

* Read before the Photographic Society of Great Britain.

which is practically non-actinic. It is this mixture that I recommend for coating the shades of lamps or gas lights. Personally I would never develop a bromide film by daylight if I could use artificial light.

When we come to the bromo-iodide film, we see that the ordinary orange-glass (Fig. 9) is not quite safe to use, since it lets through some of the green rays; and that the stained red (Fig. 10) is the best glass to employ. The latter, being orange-coloured, is a nicer light to work in than that coming through ruby glass. It will be noticed that green glass (Fig. 11) is useless in any case, and that there is no advantage in any combination of it with the glasses tried. It will be seen that the red of the spectrum which traverses this glass lies near C, to which the bromide is sensitive. Stained red and green glass sometimes will give a yellow-orange tint, which perhaps may be pleasanter to the eyes than the deep orange of the light coming through the former alone. The light, however, is seriously diminished by the combination. The advertised "Non-actinic Glass, Tested by the Spectroscope," is apt to mislead the unwary; the diagrams above, it is hoped, will enlighten the photographic public.

Before concluding, I would wish to touch upon a recent—what I may call—controversy, regarding the employment of fluorescent bodies to cut off what is called actinic light. Hunt, in very early days, in his researches on light, called attention to the action of sulphate of quinine, and it might have been thought that this ghost of a fallacy would have been effectually laid many years ago. It has cropped up again, however, and in a refutation of the fallacy some astounding statements have been made, which, if true, would have made it necessary to reconsider the theory of fluorescence. I pass this by, however, and show you what really does occur. In this photograph, half the slit was exposed to unshielded sunlight (Fig. 13), and half to sunlight screened by a cell containing a solution of sulphate of quinine (Fig. 14). It will be noticed that the spectrum is bounded in the latter by one of the H lines at the extreme visible limits of the violet. In other words, the solution of sulphate of quinine cuts off the ultra violet rays, and no others.

It is to be hoped that this result may convince photographers in general of the futility of using such solutions to cut off those rays which can perform work as chemical action in silver salts, unless a silver salt be found which is only sensitive to the rays so cut off. A search for such a compound would hardly repay the trouble.

I would draw attention of the members to the fact that the production of these illustrative photographs is due to my discovery of the preparation of silver bromide, which is sensitive to all radiations, from the ultra red to the ultra violet.

LIGHT, AND ITS WORK IN ABSORPTION.

BY CAPT. W. DE W. ABNEY, R.E., F.R.S.*

LET us now, while we have the last beautiful experiment in our mind's eye, endeavour to see what has taken place. If I take one of the leaves of this scarlet flower and examine it by transmitted light, I find it red, that is, it absorbs the blue and yellow to a great extent. How, then, is it that we see it red by light which is reflected from it? Surely if it allows the red to pass through it, you would suppose that the light reflected would not be that which it transmitted.

Let me endeavour to explain this by an experiment. Here I have a liquid which, by transmitted light, is red; I hold a sheet of white paper behind it, it is still red; but now I place a black cloth behind it, and allow the light to shine on it. The colour is gone—it appears very nearly black. I still keep the cloth in its place, and sift some fine powdered chalk into the fluid. Immediately we have

the tracks of the chalk particles illuminated with a red light. The red colour starts into visibility. Why is this? The small white particles of chalk act as so many mirrors—they reflect back the light shining on the particles. In going and returning, the light passes through a medium which absorbs all but the red light, and consequently the reflected light which re-enters the eye is red. Apply this to our red leaf. A leaf under the microscope appears as built up of innumerable cells, each of which contains a red fluid. The white light reaches the interior of the leaf, and the light which passes through the cells then is robbed of all except the red light. Passing through the fluid and the cell sheath it comes in contact with another colourless cell sheath, part of the light is reflected, and part transmitted through to other cells. Nearly all the light reflected has passed through the red fluid, and therefore reaches the eye of the same colour as that which the fluid transmits.

It is the *irregularity* of the cells which causes the light which reaches the eye to see the same colour as that which the leaf transmits. I will briefly explain the changes which occur in the white flower when placed in the spectrum. In white light the fluid in the cells transmits rays of every colour composing white light. When in the red part the ordinarily colourless fluid in the cells transmits the red, and the irregularity of the cell tissues causes the transmitted light to be reflected, hence it appears red, and so on.

So with our red book, the fibres reflect the colour which the capillary tubes hold in their tenacious grasp.

Perhaps the following experiments will aid us in our conception. Here I have differently coloured cardboards. One by one I place them at an angle with the lamp. The light is reflected from their surface on to another sheet of white card. The latter, it will be seen, takes the hue of the former.

In the case of metals we have a different phenomenon. Take gold, for instance; it reflects yellow light to our eyes. Our senses tell us that we cannot see through a sovereign; but by mechanically rolling we can reduce gold to a thickness in which it is transparent; 280,000 of these transparent leaves piled one on the top of another would reach to the height of one inch. When a film of this metal is placed in front of the light we see that the gold has a green tint by transmitted light. If gold behaved like our scarlet flower it would reflect green light. If we take away the green from the pure spectrum, and recombine the remainder, we should evidently get a purplish tint; and supposing that the gold reflected the light which it partially absorbed we should see gold of a purple colour.

We may go a stage further, however, and show you that in the green tint we have probably other colours. Here I have a film of gold, which is produced by acting on metallic silver with a solution of chloride of gold. The gold occupied the position of the silver, and the silver chloride formed was dissolved away. In this case the film is of a fine purple colour. Again, here I have a very dilute solution of a salt of gold, and if I carefully reduce it to the metallic state whilst in solution we shall find that sulphate of iron, and you see that my surmise is correct. Now then; suppose we take away the blue and the red which form the purple, from the spectrum, and the green which shows so markedly by transmitted light, we shall get nothing but yellow left, and this agrees pretty well with the reflected light of the gold.

Silver, again, which in thin films transmits indigo light, can be made to assume a reddish and a greenish colour by transmitted light, and when these are abstracted from the spectrum we shall have whitish light remaining, which corresponds to the colour of silver. In other words, the colours which are not transmitted are reflected, and we get a case of selective reflection.

There are some other bodies which show this selective or metallic reflection. This magenta dye, for instance, I have mixed with collodion, and it transmits red and a little

*Concluded from p. 113.

indigo. I have coated a thick glass plate with this colloid, and use the glass surface as a reflector to reflect the slit of the lamp upon the screen.

In fig. 3, G H is the thick glass, S the slit of the lamp, through which a beam of light passes to *a a* on the first surface of the glass, H H H H; thence the beam is reflected going through the lens L, by which it is focussed on the screen, giving an image, A A, of the slit. Another part of the beam is refracted to the back surface, G G G G, of the glass plate, which is coated with the dye, and is reflected from *b b*. It again is refracted at *b' b'*, and passes through the lens L, forming an image, B B, of the slit on the screen. The first image is perfectly white, since the light is reflected from the front of the glass; the last image tells us of the character of the light reflected by the dye. In the case of the dye we are now experimenting with we should find, if analysed by a prism, that the colours reflected were complementary to the colours transmitted, the image from the surface of the glass covered with the dye being of a blue green tint.

Here is another dye, which, like the last, when looked at in lumps, has a metallic lustre; by transmitted light it is purple; but when put before the lantern in a film behind the glass, we see that it reflects an olive-green tint. Dyes which have not this metallic lustre do not act in the same way. This dye transmits yellow, and you will see that it reflects yellow light. The reason of this difference in the powers of reflection is somewhat obscure at present; but we may hope soon to obtain more information on this subject. Applying the principle of work to metallic reflection, it will appear evident that there will be less heating and chemical action in those bodies which exhibit it than in those which absorb the rays, for in one case certain waves are only driven back, and do no work in the body, whilst in the other they are absolutely extinguished.

We may state that ordinary materials met with in nature, as a rule, reflect the transmitted light, and that the cases of metallic reflection occur but seldom, and may be looked upon as peculiar exceptions.

I have now come to the end of my task. I have endeavoured to give you an idea of light, and what it is, and the effect of material matter upon it. We have seen that the energy carried by light either from the most distant star, or other source of light, such as a candle or lamp, is, as a rule, partially absorbed by the object on which it falls, and does work of some kind in that object.

Suppose it had pleased the Author of nature to have made a law that no absorption should take place. How uninteresting to our eyes, as at present constituted, would the world appear! The absence of colour would rob us of the very poetry of our existence, that poetry which is innate in every mind. No glorious sunsets, no blue sky, no rainbow, no green fields, no lovely landscapes with mellow distances, would charm us. The earth would be bereft of all her artistic beauty; [and if there were no absorption we should have to exist in that icy cold which we can only reason about, and have never felt.

It may, perhaps, be said that such an absence is impossible. It is owing to the wise Providence that watches over us, but it is part of the business of science and men of science to realize what the effects of such an impossibility would be, and to lead the mind to grasp how kind, how beneficent, is the Ruler of the universe and the Giver of its laws.

THE USE OF SALICYLIC ACID IN PHOTOGRAPHY; ITS SPECIAL APPLICATION TO CARBON PRINTING AND GELATINE PROCESSES. BY DAVID BACHRACH, JR.*

FOR more than a year I have been experimenting with various of the well-known antiseptics introduced of late by chemists with a view of working, with something like certainty, carbon tissue during the five months, at least, when the thermometer gets above 80° in our climate. Our establishment is one of the thirteen who bought the Lambert Processes in Baltimore, and is the only one now using it regularly, and then only for porcelain miniatures and the reproduction or enlargement of negatives. Like the vast majority of those who bought, we consider it utterly impracticable as compared to silver printing for regular commercial work, but hope to see the day when it will become practical for general use, for the sake of its undoubted permanence when properly practised. The process as given out by Lambert we pronounce (and we are of the majority), so far as the extravagant claims made for it by him are concerned, utterly unreliable in this latitude at least five months in the year. Yet it was so desirable to us for the purposes we use it, that I instituted a careful series of experiments to overcome the difficulties. From long experiments with gelatine work in the photo-engraving process, it was not long before I found that carbon tissue acted precisely similar to the gelatine films in certain kinds of weather. Gelatine, glue, and similar substances undergo a peculiar sort of decomposition in the presence of the chrome salts when the thermometer reaches 80° and upwards, and especially in what is termed muggy weather, when the atmosphere is filled with moisture. This takes place when the sensitized tissue is in a moist state, when drying, and continues more slowly when fully dry.

The film when examined under a microscope presents peculiar granulations well known to chemists, and very similar to those presented when such organic substances are decomposing and full of animalcules. Ice used in the bichromate solution does not do a particle of good unless the film is dried at a very low temperature, when the atmosphere favors such decomposition. I find further that such gelatine, even where it has been acted on by light, will afterwards be liable to decompose and run together, as two miniatures made under such circumstances have been returned to us utterly spoiled. I also find that when the film was in good normal condition, and not decomposed, the pictures would stand the severest tests. The remedy, then, was evidently to be found in this direction: to find a substance that would act as a perfect antiseptic, and not affect the general result otherwise. After trying almost all the substances known in practical chemistry for this purpose with but limited success, I concluded to try the latest of them all, which I found just the thing. Salicylic acid is another of the wonderful products of the distillation of coal tar, and is similar in some properties to carbolic acid, but with none of the objectionable features of the latter. I dissolve salicylic acid in about an ounce of alcohol to a half gallon of the bichromate sensitizing solution, sufficient to give from one to one and a half grains of the acid to every ounce of the latter solution in hot weather, and about half the quantity in cold weather. It is necessary in this case to use somewhat more of the bichromate to the same quantity of water, as the salicylic acid makes it slightly less sensitive, and makes the contrasts stronger, with the

* *Anthony's Photographic Bulletin.*

solution as usual. One who has not tried it has no idea of the benefit to be derived from its use. In cold weather sensitized tissue may thus be kept indefinitely with the least care in perfect condition, as soluble in a month as on the first day; and during the latter part of last summer, when I first used it, I kept the tissue perfectly good for over a week, something I had never been able to do before; and how much longer it would have kept I cannot as yet tell.* All reticulation disappears, and you can rely on every piece of tissue without waste. And the beauty of it is, it is always of the same degree of sensitiveness, and does not vary. In fact, this substance keeps gelatine in its normal condition, subject only to the change effected by exposure to light. Of course I cannot yet tell whether the proportions I have given are the best, but I hope to hear further and have more light thrown upon the subject by other experimenters. With this substance it is not only possible, but, I think, preferable, to use the bichromate of ammonia, a more sensitive salt and giving greater detail than the bichromate of potassium. It must be remembered that the acid acts also as a restrainer, and consequently with the same strength of solution will give harsher results than when the solution is used plain. I also use some glycerine in the sensitizing solution, to prevent the tissue from becoming horny and liable to crack in extreme cold weather. In working with tissue one thing is necessary to bear in mind: if dried at too high a temperature, and too rapidly, it has a tendency to wash out and lose detail in the whites and work with great harshness, giving a condition of film very undesirable, and causing many failures in the double transfer. It has under such circumstances a dull surface, lacks all brilliancy, and loses the fine, smooth surface of the film in the normal condition. Of course salicylic acid tends to prevent this to any great degree, even under such circumstances; but it will certainly prevent it at ordinary summer heat. The salts of the acid, such as the well known salicylate of soda, seem not to retain any of the antiseptic properties of the acid, and I have as yet not found them available as a substitute. They would have the advantage of being soluble in water and not affecting the sensitizing solution in the least, though I have had no perceptible trouble on that score. It is very desirable to use the ammonia bichromate in preference to the other, when found practicable, on account of its more careful and uniform manufacture, not being such an article of commerce as the potash salt, and consequently acting more uniformly as well as having less tendency to work harshly.

In experimenting further, I found that salicylic acid was very valuable to use in summer for keeping sensitized plain paper from the rapid decomposition to which it is liable when used with ammonia-nitrate of silver. I use two grains to each ounce of salting solution, and have not had the paper decompose and turn hopelessly yellow on the solar camera board since. In extremely hot weather it has often done so when using a negative that required a long exposure to print. It seems to have no perceptible effect on the sensitiveness of the paper when used in the quantity indicated. I have also used it as a substitute for citric acid in the process for printing on painter's canvas which I published some years ago. It has the same beneficial effect in that, sometimes enabling us to leave a canvas on the camera over night, to be completed next day, in case of failure of light. It will also be found of value as an aid to cleanliness in the developing processes for solar enlargements, by using it as indicated in the salting solutions. Finally (but this has long been known), it is invaluable as an antiseptic for paste, gum, and gelatine solutions for use in photography, preventing decomposition and mouldiness, to which is sometimes due the fading of prints. In conclusion, I hope that others pursuing this subject may aid in perfecting and making exact its uses (which are evi-

dently manifold), and give the benefit of their researches to the fraternity.

Caution in using Salicylic Acid.—More should not be used than is required to produce the desired effect; and the proportions given are the largest quantities necessary. It is advisable to occasionally add a little alcohol to the sensitizing solution to make up for loss by evaporation, otherwise the salicylic acid will separate as a flocculent precipitate, it not being soluble in water. Whenever this precipitate forms, a little alcohol added to the solution and well shaken will redissolve it. It would undoubtedly be preferable if one of the combinations of the acid with a base, to form a neutral salt solution in water, could be made to serve the same purpose, but the writer thus far has had no time to experiment in this direction, and hopes that others will find such a substitute and publish it. A combination of the acid with lime, forming salicylate of lime, would seem to be a good direction to experiment in; but in cold weather there is no practical means of fully testing it, as there is then but little trouble with tissue. Such a salt has the advantage of not affecting the sensitizing solution in the least, while with the acid a stronger solution is necessary to avoid too much contrast and prevent the light tints from washing out.

NEW PATENT BILL.

WE append the following summary of the principal provisions of the new Patent Bill introduced into Parliament.

1st. The duration of provisional protection is to be extended from six months to one year, and the stamp duties thereon lowered to half their present amount.

2nd. A complete specification must, however, be filed before the expiration of nine months from date of original application, or the protection will terminate at the end of the twelfth months, and cannot afterwards be renewed.

3rd. The complete specification shall be immediately published, with all other documents relating to the case, and for a prescribed period anyone shall be at liberty to oppose the grant of a patent.

4th. If there be no opposition, the applicant may give notice to proceed, and secure his patent, for half the stamp duties now levied.

5th. A patent shall last for twenty-one years instead of fourteen, but shall become void if the £50 and £100 stamps be not duly paid at the end of the third and seventh years respectively, and an additional stamp of £100 before the end of the twelfth year.

6th. Patents can be amended or added to hereafter, but with such fees and limitations as to make an amendment—especially if an addition—almost as costly as an original patent. The amendment, however, then becoming part of the original patent, is not subject to additional stamp duties (this, however, is still a great improvement over existing practice, and all alterations mentioned so far are in favour of the patentee.)

7th. The Crown shall have power to use any patented invention, paying the inventor such royalty as the Treasury shall consider fair.

8th. If an inventor do not work his invention in the country within three years of grant, and if he refuses to grant licences on such terms as the Lord Chancellor shall consider reasonable, the patent will be annulled.

9th. Inventions first patented (or imported from) abroad can in future be patented in England by the foreign patentee (he being the true and first inventor) within six months of the date of the foreign patent, or of the date of this Act. But such patents will fall with the expiration of any foreign patent for the same invention, whether granted before or after date of such patent.

10th. The Lord Chancellor shall have power, in certain cases, to allow a patentee who has accidentally omitted to pay his tax in time, to pay it within three months after it became due, and thereby save his patent.

11th. All patents applied for before the passing of the Act to be independent of all its provisions except Article 10.

12th. The modes of procedure are altered in many respects interesting only to patent agents and lawyers.

W. P. THOMPSON & Co., *Solicitors of Patents,*
323, High Holborn, London, and 6, Lord Street, Liverpool.

* In a subsequent letter Mr. Bachrach informs us that he had developed tissue after having been sensitized for six weeks.—Ed. A. P. B.

PHOTOGRAPHIC REPRODUCTION OF SHAKESPEARE QUARTOS.

THERE is no purpose, perhaps, to which photography can be applied in which its capacity of accurate copying becomes more valuable than when it is employed for reproduction of old and unique documents. Whether the interest of the document be of a legal or a literary kind, unchallengeable accuracy is of vital importance. And, apart from the actual value of this accuracy, there is another kind of interest of no mean kind in such facsimile reproductions. The eye lingers lovingly upon each quaint form of letter or archaism in spelling, and all the associations of an olden time gather round, and invest the page with a strange glamour. We have had the privilege of examining the original manuscript of some of Milton's works, kept carefully under lock and key in the library of Trinity College, Cambridge; and we have the good fortune to possess a lithographed facsimile of one of these manuscripts. It is admirably copied by the hand of an expert in such work; but although admirably done, and not without interest as a good copy, it possesses none of the special interest of the original, in which every line was traced by the hands of the master; nor does it possess the interest of a photographic facsimile, which seems to be in some sort a part of the original, and only less in interest than the original. Photography has already done much good service in this way, but in nothing, probably, has its work exceeded in interest some of the reproductions, as photo-lithographed facsimiles, of original editions of Shakespeare's works. The photo-lithographed copy of the first folio, in all respects a facsimile of the edition of 1623, is a work of rare value. A similar copy in a reduced size, published a few years ago, which, oddly enough, we have never seen, was also a very valuable boon to the student of Shakespeare. But probably nothing exceeds in interest and value the series of facsimiles of the original quartos, which were the first published copies of the respective works, and were the only copies issued during the author's life. The project is to issue the thirty-five quartos, each in photographic facsimile, from the best accessible copies. The project will be carried out under the superintendence of Mr. J. F. Furnivall, an enthusiastic Shakespeare scholar; and, what is of more importance, the photo-lithography will be executed by Mr. W. Griggs, who is known as an expert of rare skill and experience in this branch of work. The volumes will be issued at six shillings each in cloth with morocco back, and when it is remembered that an attempt at hand-traced facsimiles were issued at five guineas each by Mr. Haliwell, some years ago, the value to Shakespeare students of the present issue may to some extent be estimated.

The first of the series, just issued, is the facsimile of the Hamlet of 1603, manifestly a first and very crude sketch of the completed and matured work, but of inestimable value as an aid to the study of the completed play, which will form the next volume of the series. The work is exceedingly well done, and singularly even and uniform in effect. It will, we doubt not, be greeted with much pleasure by all Shakespeare scholars and students, as the most valuable aid to the accurate and satisfactory study of Shakespeare which has hitherto been issued.

Critical Notices.

THE NEW PRACTICAL PHOTOGRAPHIC ALMANAC for 1879. Edited by J. H. FITZGIBBON, St. Louis.

SINCE we sent out the first issue of our annual it has had a numerous following, in this country and in Continental Europe and America; but there has been none more full of genuine practical interest than the first yearly venture of our friend Fitzgibbon, now before us. It is very essentially *practical*, as it aims to be. It contains excellent contributions from men of high position on both sides of the water. We were about to conclude by recommending the little work to our readers, when we remembered that it was not published or readily accessible on this side of the water: so we substitute for that recommendation a promise to lay extracts from time to time before our readers.

A POCKET-BOOK FOR CHEMISTS, PHOTOGRAPHIC STUDENTS, &c., &c. By THOMAS BAYLEY, Assoc., R.C. Se. J. (London: E. & F. N. Spon.)

THE little book before us is one of the most valuable reference books on all technical points interesting to the chemist that we have met with: tables of every kind, and detailed conversions of grammes into grains and similar matters; solubilities of bodies, specific gravities, boiling points, standard solutions for purposes of analysis, &c., &c. It will frequently save the experimentalist much trouble and waste of time, and is worthy of all commendation.

FRENCH CORRESPONDENCE.

INVENTORS IN THE PHOTOGRAPHIC SECTION OF THE LATE INTERNATIONAL EXHIBITION.

BROUGHT face to face with the movement for the erection of a monument to the memory of Nicephore Niepce, we naturally think of the numerous inventors who have enriched the photographic art with the results of their unweary labours. Justice is always late in being done to those indefatigable inquirers who fight in the front rank against prejudice and incredulity, and who often, in this life, reap no other reward but misery. The acquisition of fame and distinction has occasionally not preserved inventors from dying of hunger, and there are many who never lived to reap their long-coveted honours. There seems to be a fatality attending them, and an Edison, who is able to fill the whole world with the *eclat* of his successes, is in reality an exception to the rule. For example, honours are only awarded to Nicephore Niepce many years after his death; and in doing this even—excellent as the intention may be—we are committing a wrong, for we are separating his memory from that of his fellow-worker in the heliographic art, the illustrious Daguerre. Why should the fame of the one be celebrated to the exclusion of the other? Is the present generation, in its endeavours to appear grateful, to deprive Daguerre of the honour of an invention that was almost simultaneous with the discovery of Nicephore Niepce? If we hold the latter to be alone deserving of public admiration, are we not denying

any value at all to the work of the former? And in that case, how comes it that even during his lifetime he was permitted to claim his great invention as his own, and to confer on it the name of Dagnerrcotype? These questions seem to me to have a logical significance, and it may be that the facts of a tardy reparation, with their own brilliant eloquence, will come to resolve them at the proper time and place. It may be said of inventors as of saints—a certain time must elapse before they can be canonised.

The unfortunate fate that clings to all inventors has once more manifested itself at the Paris Exhibition, and I am not sorry that the subscription for the monument to Nicéphore Niepce affords me an opportunity of awarding to them the well-deserved tribute of praise which the jurors seem to have forgotten to bestow on them. I may be allowed on this occasion to give a short retrospective review of the labours of the artists who have devoted themselves to the advancement of photography without having received the pleasure of an official recognition, in the hope that it can only be of benefit to those immediately concerned, asking, at the same time, pardon of the readers of the PHOTOGRAPHIC NEWS for entertaining them with the details of a now defunct exhibition.

Much talk has been occasioned by the numerous complaints to which the award of prizes by the photographic section of the International jury gave rise. Only the other day, one of my colleagues mentioned the extraordinary fact that Mr. Seavey, whose photographic backgrounds are celebrated all the world over, had only been adjudged a bronze medal, or—as this massive distinction is called here in derision—a medal of chocolate. Certainly, any one who has had the opportunity of listening on the spot to these complaints must have been struck by their reasonableness, and, notwithstanding the anxious attempts to stifle them, it cannot be denied that they have produced a very bad effect on that portion of the public that is in a position to judge.

M. Michaud has invented a new process of photo-engraving which has already been described in your columns: he has not even been thought worthy of a mention. M. Pellet, who has been repeatedly spoken of in the PHOTOGRAPHIC NEWS, exhibited some of the prints taken on his *papier cyanofere*: not the slightest allusion is made to his ingenious invention. M. Billon-Daguerre showed photographs taken on wood, from which the engravers could work directly on the block, without having, as heretofore, to cut only from the drawing of the artist: the jurors took no more notice of them than if they had been the boots of the gallery attendant. M. J. Vallette submitted to the notice of the jury an excellent travelling camera, very simple and portable, and meeting every requirement: he has been "hit over the head" with an honourable mention. A novel apparatus for washing films, designed by M. Couture de Rilly-la-Montagne, has, as it really deserves, met with the approval of all competent judges; but from the official jury it has received nothing but the attention of being relegated to a remote corner of the gallery where the photographic section was exhibited, and no award of any kind was conferred on it. A very skilful carver in wood, M. Boulanger, has devoted his attention to making posing furniture for photographers, and has turned out some pieces which are perfect models of taste. Imagine what to all appearance is a simple column, but which in a few seconds can be converted into a stand or a table, or a counterfeit chimney piece, or a *prie-dieu*, or an ottoman, or a bookcase, or even a piano! Some of M. Boulanger's accessories are capable of no less than sixteen transformations, and scarcely occupy the room of a small child. This manufacture as it is carried out is really an artistic one, and is almost unique of its kind: but M. Boulanger has not been thought worthy of even the shred of a prize. Notwithstanding this want of appreciation on the part of the jury, however, the accessory furniture that I have described has, as I am in a position to assure you, excited

universal admiration. I could bring forward other instances of this spirit of ostracism in which the jurors have dealt with inventors; but of what use would it be to do so? The list itself ought to be a sufficient answer to any who object to my criticism.

One inventor alone, M. Poiteviu, has received a consideration commensurate with his merit. It is true he has not exhibited anything specially worthy of note, but a number of pictures taken by the various processes that he has discovered were very conspicuous in the photographic section. To him, in the capacity of *collaborateur*, was awarded the medal of honour. The bestowal of this very high distinction has been received with unanimous applause in all quarters, for it is a legitimate honour to crown a long career entirely devoted to researches in the science and art of photography. This award to M. Poiteviu was a foregone conclusion; it was impossible to do otherwise than confer it on him.

I believe it will not be without interest thus to have pointed out the indifference of which inventors have been the victims. It seems to me impossible to insist enough how strongly those are deserving of reward who show at our exhibitions novel applications and valuable discoveries. We live at a time when things which meet with a certain amount of appreciation have to be highly paid for. It is quite sufficient to declare that some secret process has been discovered for obtaining specially artistic prints, to puff some new formula for extra-rapid working, to vaunt imaginary means of obtaining magnificent proofs with a very short exposure, and to call all these processes by high-sounding names, in order to realize a fortune much more quickly than by good photographic work. No consideration is given to the facts that the most valuable secrets are acquired by personal experience and daily study; that they much depend on the excellence of our apparatus and re-agents, and are paid for without knowing it. It would be more advisable to render the proper tribute of justice to the inventors and their valuable discoveries.

(To be continued.)

THE USE OF DRY PLATES IN THE STUDIO.

BY C. FERRANTI.

A PERUSAL of what has been written on this subject tends to show that absolute immunity from failure can hardly be expected for the dry-plate any more than for any other process brought to bear upon so many and constantly varying causes, too well understood to require enumeration.

That failure can be reduced to a minimum and is a point gained in favour of good dry plates, has been amply ascertained when a desire has existed to arrive at a truthful conclusion. Until by practice and experience a thorough knowledge of the best mode of working with dry plates has been acquired, it will certainly be a advisable to have at hand the bath and collodion.

The yellowish green hue, the wrinkling or frilling of the film, too intense negatives, and, maybe, a few other trifling vexations, are all things to be expected at first. We may here quote the appropriate words of the good Vicar of Wakefield: "We were very bappy, not but that we sometimes had those little rubs which Providence sent us to enhance the value of its favours." Still there is this difference: the little rubs of Providence cannot very easily be averted, whereas we can more easily find remedies for our little photographic troubles.

We will endeavour to give some information on the subject of these difficulties, which ought not to dishearten, and should be well understood before confidence can exist in the mind of the dry plate worker who want to make sure of good results. *The yellowish green hue* may be the result of over-exposure; in such a case, thin plates of this description must be looked for; it may also happen that the developer has not been well managed; and again, the plate may have been bad. Comparative trials

tend to prove that over-exposure is oftener the fault. In the case of a ferrous oxalate developer, and where it has been used over and over again without sufficient addition of fresh stock, it may happen that it has lost its energy; in such a case, the failure suggests the remedy.

Wishing to investigate the matter thoroughly, the writer noted that somewhat thin and unsatisfactory negatives had been produced under conditions known to experienced and observant photographers to yield harder and less satisfactory negatives with the bath and collodion; subsequent experiments proved that even under the conditions of a very bright sky, with a cold east wind blowing, the sum of advantages was so greatly in favour of dry plates that excellent negatives could be produced with a remarkably short exposure.

We have advocated the use of ferrous oxalate for many reasons, of which not the least is the fact that it will not have the injurious effects which must be anticipated from the fumes of strong ammonia. Its great simplicity brings one back to the days of iron development in flat dishes, the solution being used over and over again. This simple method was afterwards abandoned, probably for the same reason as that given by those who pin their faith on the belief that by skilful pourings on and off, certain magical and artistical effects can be produced. It is not, however, our purpose to enter into questions of so delicate a nature at present; we will confine ourselves to stating that very beautiful results can be obtained by the means advocated, and that a better or simpler method could hardly be desired by the practical operator who expects the camera, aided by his chemicals, to reproduce faithfully and thoroughly the conception of his brain.

Wrinkling or Frilling of the Film.—In a former article on this subject the means of avoiding such a mishap have been given, and as it is a perfect cure it may prove useful to state more in detail that after development the negative must be slightly washed, and then allowed to remain in the alum dish from one to two minutes. Wash again, and fix thoroughly. When the plate has been cleared of every trace of mottling, it can be again washed, and must be plunged a second time in the alum bath, where it should be left for at least five minutes, and then finally well washed. A close adherence to the above instructions will prove satisfactory in every way.

Too Intense Negatives.—In most instances this defect will be due to a want of correct appreciation of intensity, or from allowing the developer to act too long on the film. A properly timed negative under favourable circumstances develops very rapidly, and requires attention. A little practice will work wonders in this case. It may prove useful to state here what has been found a practical method of working rapidly and with certainty. Three white porcelain flat dishes are required. The first, in which the developing solution is contained, should be slightly larger than the plates used; the second, in which the alum bath is kept, should be large enough to hold four plates; and the third, for hypo, should be of the same size. The water-tap should be close at hand. It will be seen at once that with the arrangement suggested, and by using for each dish a small piece of wood about six inches in length and tapered at both ends, the fingers need scarcely touch the solutions, and the necessary motion can be imparted to the plate during development. The plate can also be examined several times without danger whilst it is being developed. Every operator will know how best to suit arrangements to his own convenience.

We may have an opportunity of stating shortly our opinion on some other supposed difficulties and objections.

Correspondence.

PHOTOGRAPHY BY ARTIFICIAL LIGHT.

SIR,—I have been in the habit of perusing your NEWS, searching for crumbs of information and encouragement from the experiences of my brother artists, and in days gone by I have reaped much benefit from its pages; but

lately there has been little else to read but articles, correspondence, and advertisements relating to the artificial light mania, after the perusal of which my mind will revert to that clever satire by the late Tom Hood, in his little book entitled "From Nowhere to the North Pole," in which the reader and Master Frank, the hero of the tale, are introduced by the Fairy to "The Undernational Exhibition, or The Hall of Idle Inventions," amongst which is an elaborate scheme for "making malachite buttons from mushrooms."

An estimate is prepared, after the reader and Frank have visited the process in all its stages, showing the cost of growing the raw material, painting, veining, polishing, shanking, &c.

"But," says Frank, "if your buttons cost that, what do real malachite buttons cost?"

"Ah! That I don't know," says the inventor; "haven't any idea."

Now an estimate of the expense, and some idea of the difficulty, has been drawn up respecting the electric light—notably, by Dr. Drinkwater, F.C.S.—which amounts at least to £200, whereas daylight costs nothing*; or, taking the cheaper method of artificially illuminating the sitter (say the Luxograph patent), it will run to £40 or £50 at the least, and it will take many sitters who "cannot call again" to reimburse that outlay. Besides, it is my opinion that the said sitter, on comparing his artificial light picture with that of his friend's pictures taken by daylight, will invariably find time to call again, and have one taken by daylight, and so get a photograph of himself representing him as a living being, with all the half-tones, lines, and texture of the skin depicted, instead of an unnatural waxy skin, glassy eyes, false and reflected lights, black shadows, and the entire appearance very supernatural and corpse-like; for such are the characteristics of these artificial light pictures—at least, all that I have seen. And supposing the artificial light is eventually brought to something like perfection, I cannot see where the gain is to come in, only in the satisfaction of having mastered a scientific problem, or for enlarging purposes; for, as is well known, in dark weather it is always accompanied by rain, fog, drizzle, mist, and snow—one or the other—with an extensive accumulation of mud underfoot, and great discomfort is felt in going far away from home; so our sitters stay indoors, and I believe they would even if the light was good, in face of all these discomforts and annoyances and risk of taking cold, particularly with children, who are, as a rule, our best and prettiest subjects.

This artificial light might draw them out while the thing is new, just for a week or so, and then there is an end of it.

Then sitting for a photograph, with nine persons out of ten, is a holiday event, or when on a visit to a friend in your town, who recommends you to her visitor; or when the necessary duties of life allow you a little spare time, it comes in then as a part of the holiday recreation; and people are not in the habit of taking holiday and donning their best attire on dull, dark, rainy days, and no sane person would think of using the expensive, uncertain artificial light when the real genuine article is to be had for nothing; and if it is not to be had just when your sitters call, send them away to call again when there is daylight; then get a good result. "The best picture they ever had." Your sitters will then honour your independence and self-denial in risking the return of their patronage for the sake of your love of art and a good result. Depend upon it they will come again, and, what is more, will send their friends. Treat them the same, always pleasing them; they

* Is our correspondent prepared to supply it in unlimited quantities on these terms? If not he should not quarrel with those who try to eke out the limited supply by any adequate substitution. If he do not require such aid, he assuredly will not be tempted to purchase it; and may enjoy a happy smile at the poor wretches who are foolish enough to gain a few shillings at the outlay of a few pence.—Ed.

in their turn will speak well of you, and so the ball is kept rolling.

I am sure there are plenty of photographers, judging from their work and the finish thereof, whose time would be well employed during the slack, bad season, in improving their studios, reception rooms, and plant: cleaning, painting, doing up their accessories, studying posing and lighting from works worth imitating; re-modelling their dark and printing rooms, system of doing business, registering and preserving their negatives, &c., &c., so that their next season's work shall be a great improvement on the past. This is what is needed. Perfect what you do know, aided by hints and ideas from those who excel in their productions; and last, though far from least necessary, your own brains, instead of this feverish excitement after a novelty which, in the end, in most persons' hands, if not all, will bring no profit, and, what is most important, will not improve their work; because I am certain that those who cannot take a good negative in a real artistic sense (not a mechanical or manipulatory sense) by daylight, cannot by the artificial light, which is a thousand times more difficult, and requires more artistic knowledge of light and shade by far to achieve even a bad daylight picture by its means.

Now, none of those artists who excel in the work—such as Mora, Sarony (both of New York), Slingsby (of Lincoln), Abel Lewis and Marshal Wane (of the Isle of Man), and others, have anything to say, and take no part whatever in this artificial light discussion. I think this fact speaks volumes. So let us look about us and strive after good work with the means we possess, instead of wasting time and money and space in the NEWS, hunting up inferior artificial means of doing the work when we are already possessed of the efficient natural means.

I hope I have employed the dull, long winter to good purpose, gathering ideas, &c., to be put in practical shape ere long, and setting my house in order; and to show that I am not the proverbial guide post, pointing others the way, and never going myself, I propose sending you some of my new work to inspect and criticise, if you will favour me by accepting it.—Yours very truly,

DECOR INENPTUS.

DEAR SIR,—Having read a great deal lately in your valuable pages about artificial light for photography, I thought the following account of a light used as long ago as 1856 might interest some of your readers. I had it from the *Family Herald* for October 18th, 1856, and it is as follows:—“A very brilliant light has been produced by directing a stream of oxygen gas into the flame of coal gas which had been previously passed through cotton and naphtha. In order to surcharge it with carbon. With this light, using a reflector, a photograph of an engraving was taken in a very short period.” Thinking that this light somewhat resembles the oxyhydrogen light, I have sent these lines hoping they may be of practical use to some of your readers, though of none at present to yours truly, J. L. BERRY.

1, Market Street, Aberdeen.

FIXING THE EYE IN PORTRAITURE.—PORTRAITS BY ARTIFICIAL LIGHT.

SIR,—It appears, from the paragraph you quote from the *Danbury News*, that the American photographers are recommended to try the clock face idea for making the sittings for one's portrait more pleasant.

It will be seen, by referring to the last PHOTOGRAPHIC NEWS ALMANAC, that I have recommended and adopted an improvement on the idea alluded to, and if you will kindly reproduce the two engravings, and let them appear with this letter, I shall be glad for the suggestion to have the benefit of the extended circulation of the NEWS.

The two sketches speak for themselves. I need only

say that the revolving aperture *compels* the eye to follow, which it is not certain to do if the sitter is merely required to look alternately at the figures on the open dial.

I ought, perhaps, to say that the little piece of apparatus was made for me by Messrs. Cussous and Co., of Southport.

Dr. Drinkwater, in his paper on the application of artificial light in photography, refers to the use of magnesium having been abandoned on account of its expense. From some experiments lately tried, I find the cost to be about 2½d. for each exposure. At the time my first experiments were made I think the cost was 1s. It will, I believe, be found on careful trial that no light equals the magnesium in cheapness and ease of application.—Yours truly,

A. BROTHERS.

THE USE OF GELATINE DRY PLATES IN THE STUDIO.

DEAR SIR,—As the use of dry plates in the studio is rapidly growing in importance, I beg to add a little of my own experience to the many useful hints that have appeared in the NEWS the last few weeks; but lest it should be supposed I am making a claim for priority of use, I will at once state such is not my intention.

I totally abandoned the silver bath for all studio work in September last, and the ferrous-oxalate has since occupied its place. I have tried commercially prepared plates, but since September I have made my own. It is not my intention to say anything of the process beyond stating that ample instructions have appeared in the NEWS. The process of Mr. Bennett I have tried, and can recommend it to any, wishing to make their own plates, as excellent.

I now come to the object for which I write, namely, the method of development I have used in preference to all others since November last. I lay no claim to its origin, the formula having appeared in the NEWS, but may have escaped notice. It has the following advantages over the ordinary oxalate bath: namely, you can make a stock solution that will keep for a month or more; it develops quicker; and after the iron is added, it will keep in good developing action for three or four days—in fact, I have used it at the end of a week after standing all the time in the dipping bath. I hope some dry plate worker will give it a trial. I append the formula:—

To twelve ounces of boiling water, add three ounces of salts of tartar (to this while hot), add oxalic acid until effervescence ceases; if found too acid, add a little more salts of tartar until about neutral; this is stock solution which will keep. To make the developer, add to each ounce of the above twenty grains of proto-sulphate of iron.—Yours truly,

J. B. CLARKE.

Thirsk.

AN UNTRUSTWORTHY OPERATOR.

DEAR SIR,—Under the above heading, in last week's PHOTOGRAPHIC NEWS, you insert a letter from a correspondent giving his experience of photographers' assistants

during a period of over twenty years. In that time he has had, to quote his own words, "occasion to employ quite twenty assistants at various times. All (save one) turned out either *ungrateful* or dishonest." He then relates his last experience—a serious case of theft. This you consider "all operators are concerned in discovering, if possible, and certainly disowning."

Thus called on, I would ask by what right we should be called upon to disown a thief? Are operators regarded as being of such doubtful character, that whenever a case of theft occurs, they are all to be called up to disown the act, under pain of being considered as sympathising with the thief? If an employer is guilty of wrong to an assistant, are all employers also to be called upon to disown it? And will they look upon such as do not as having a fellow feeling with the culprit?

Your correspondent is certainly to be pitied for his twenty-two years' experience. There are houses that have retained their assistants as many years as he has had assistants in his twenty-two, and there are many who can point to three years and upwards of honourable employment in a single situation.

The inference conveyed by your correspondent's letter, and your own (it is to be hoped) unwitting support of such inference, is, I am convinced, not justified by the facts—theft being no more a characteristic of photographers' assistants than it is of any other class of the community. There is, therefore, no reason why they should be held up as specially responsible for the discovery or the disowning of this or any other particular thief that may turn up among photographers.

A. STACY WATSON.

[Our correspondent "doth protest too much!" As the special community in which the culprit moves, and amongst whom he claims fraternity, operators are especially called upon to "discover" or "disown" the black sheep. Especially called upon, not because that is necessary to disclaim their sympathy with crime, but because they have special opportunities of noting the tendencies and conduct of their fellows. Very especially called upon, because it has long been subject for regret that the status of photographers—especially working photographers—is not so high as it ought to be in relation to the workers in an art industry demanding exceptionally high intelligence and culture. The communication to which our correspondent refers is a pendant to one which appeared in our issue for Feb. 28th, which, although originally appearing in an American journal, details the experience in a first-class English studio which we know very well. Our correspondent does well to maintain the dignity of his order; but it is wise to remember that this is not best effected by over-sensitiveness and readiness to challenge affront where none can be intended. The PHOTOGRAPHIC NEWS has always held the position of the especial organ of professional photographers and operators, and has been proud of that position. It is the least likely in the world to undervalue the practical photographer, whatever position he may hold.—ED.]

HOW TO BUILD A CHEAP AND EFFICIENT STUDIO.

"Be warned in time by others' harm,
And you shall do full well."—*Ingoldsby.*

DEAR SIR,—A very excellent article under the above heading appeared in the YEAR-BOOK for 1879. The writer has with great clearness set forth the cost, measurement, &c., of a studio, and I have no doubt, from my own practical knowledge of the subject, that if the instructions are carefully followed, the result would be satisfactory. As the spring, however, is the time most amateur builders would think about commencing operations, a word or two of caution may not now be out of place.

If more than a certain number of feet from any house

or other building, or in the extreme suburbs, possibly such a structure as Mr. Parr describes might be erected with impunity. If in or near any town, however, I would recommend anyone about to build, first to enquire of the district surveyor if such a structure would be allowed, otherwise he may any time within (I think) six months of its erection be served with a notice to commence pulling it down within forty-eight hours, be summoned to the nearest police court, and fined £20 for having commenced building without first giving notice to the district surveyor of his intention. He will then—if he wishes the building to remain—have to petition the Metropolitan Board of Works, accompanying his communication with proper plans of what alterations he proposes in order to bring the building into conformity with the Act; may be kept in suspense two or three months, and then find that by spending about twice as much as the studio cost him, in iron, to strengthen the work and cover the unglazed portion of it, and paying the surveyor's fee, the Board will allow him to amuse himself in peace.—Yours truly,
F. A. BRIDGE.

Norfolk Road, Dalston.

[We may add a word or two to the excellent advice given by Mr. Bridge. His experience doubtless refers to the Metropolitan Building Act, a very stringent statute, but, of course, prevailing only over a given district. But the intending builder should follow the advice above given to ascertain, first of all, if a district surveyor exist, and then with what Act the building must comply. The general purport of the Metropolitan Act is to insist that the walls shall be of brick and stone of a given thickness in all parts that are not sashes and doors. In many cases it will be found convenient to build the studio all sashes and doors, and it will in some cases be found permissible. We once had a greenhouse built, the builder assuring us that he was complying with the Act. We should not have trusted him, for when completed we had a visit from the district surveyor, with an intimation that the building was not in accordance with the Act, and must come down. Fortunately we discovered that he was a good-natured and sympathetic man, and certain hints were obtained that if the boarded portion were covered with light sashes, the letter of the Act would be complied with. Our greenhouse became all sashes and doors, and passed the inspection.—ED.]

KEEPING SENSITIVE PAPER.

DEAR SIR,—In your interesting leader of the 7th instant, headed "Preserving Sensitive Paper—an Efficient Method," you say: "The early method of using a chloride of calcium case seems to have passed quite out of use. Here the preservative agency appeared to have been an atmosphere of chlorine which slowly converted the free nitrate into chloride of silver."

Agreeing with you in the observation that sensitive paper so preserved "prints slowly, and the image lacks vigour." I am inclined to attribute this defect rather to the too highly desiccated condition of the paper, than to the actual destruction of the free nitrate by chlorine, for I observed the self-same result when using my desiccating box charged with quick-lime (see *Photographic Journal*, March 1861, which could not by any possibility have destroyed the free nitrate in sensitive papers preserved in this manner, but only, by absorbing every trace of hygroscopic water, have interfered with the printing quality of such films. I found, indeed, that it was beneficial to take out the sheets a few at a time, and allow them again to absorb a certain amount of atmospheric moisture before placing them in the printing frame. This expedient enabled me to get over the difficulty to which you refer.

Commercial chloride of calcium usually contains an excess of lime rather than of free acid, and only in the latter case could any chlorine (or hydrochloric acid) be supposed to escape from the dry salt into the atmosphere of the box or

desiccating chamber. I believe the want of vigour arises solely from the excessive dryness of the sensitive surface.—
I am, yours, &c., JOHN SPILLER.

[Another highly esteemed chemical correspondent suggested that no decomposition of the chloride of calcium should take place, and with no free chlorine present the free nitrate could not be converted into chloride of silver. Our experience with this mode of keeping sensitive paper has been limited; but in the one case with which we are familiar we found a strong smell of free chlorine, and the paper presented the characters of chloride of silver without free nitrate. It is manifest our experience had been exceptional.—Ed.]

Proceedings of Societies.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

A "Popular Evening" devoted to the members and friends of this Society was held in the large hall of the Religious Institution Rooms, 172, Buchanan Street, on Thursday, the 13th inst., where there was a crowded attendance to hear a lecture and witness the exhibition by oxyhydrogen lime light of fifty photographs taken by the lecturer, Mr. James McGhie, illustrating a tour he made to Paris and the Universal Exposition, 1878.

In the absence of the President, on the motion of Mr. G. Mason, Mr. Urie was called to the chair.

The CHAIRMAN said the programme of the evening's entertainment was a lecture and exhibition of lantern transparencies illustrating a trip to Paris. The photographs were taken by Mr. J. McGhie on sensitive gelatino-bromide emulsion plates. They were exposed from Mr. McGhie's own point of view, and not for mere pictorial effect, but were the actual transcripts of the buildings and squares visited. They would give the members, perhaps, a better idea of the city than if they were actually on the spot, amid the bustle of beautiful Paris. The Chairman continued "It is encouraging to see such a large audience attending one of our popular evenings. I think it a practical demonstration in their favour, and hope by next session to see two or three similar gatherings, which, by bringing members and friends together for mutual enjoyment, will foster the harmony of the Society in no small degree. From what I know of Mr. McGhie's artistic and scientific attainments and literary ability, I feel safe in predicting an entertaining and instructive evening. From the number of slides I presume the lecture will be somewhat long. I will not encroach further on your time, but have now great pleasure in introducing Mr. McGhie, who, although the youngest, is at the same time the most talented of our members."

Mr. MCGHIE at once proceeded with his series of views, of which he gave graphic and interesting descriptions, which were received with evident appreciation by the audience.

The CHAIRMAN, in proposing a vote of thanks to Mr. McGhie, regretted that a few of the slides at the beginning had suffered somewhat by being shown out of focus, while the slight disarrangement of views had occasionally placed the lecturer at a disadvantage in his descriptions, which were elegantly composed and well delivered. The photographs he thought most admirable, bringing the buildings, squares, and monuments, &c., of *la belle France* almost in reality before them. He advised all members to follow the example set by Mr. McGhie, and bring their results before the Society; for such exhibitions, he believed, gave great pleasure, and did no little amount of good. Mr. McGhie had evidently put himself to great inconvenience and trouble in getting up the slides and lecture, and the Society ought, indeed, to feel proud of having such a useful and energetic member on its roll. He had no doubt the meeting would award the lecturer a hearty vote of thanks for having thus volunteered his services for the evening's instructive entertainment.

Mr. GILFILLAN, in seconding the vote of thanks, considered the lecture excellent in every respect, displaying in Mr. McGhie evident talent both as a photographer and a lecturer, and putting before members a fitting example which they should all strive to imitate. Such perfection and excellence, he would remind them, was only to be had by hard work. Young as he was, Mr. McGhie was already recognised as a reliable authority in almost everything photographic, and if young men wished to gain the confidence and esteem of their employers, and do a little in carrying forward the triumphs of the beautiful art-science with which they were all connected, they could not do better than emulate Mr. McGhie's example.

Mr. ROBERTSON (Hon. Secretary), in proposing a vote of thanks to Mr. Urie for the able manner in which he had fulfilled the duties of the chair, begged to coincide with everything that had already been said regarding the lecture and lecturer. He had derived a great deal of pleasure in witnessing Mr. McGhie's exhibition, the views shown bringing vividly to his recollection the beautiful sights of Paris, which he had already personally visited several times. The points of view taken by Mr. McGhie he thought really excellent, many of the monuments and buildings being thereby seemingly enhanced in beauty. The pictures in some cases seemed almost the reality, and we seemed to feel the effects of the delightful atmosphere, and he meeting the charming people of that beautiful city which no one should fail visiting. He hoped Mr. McGhie would at some future meeting give the members a full description of the process by which he had obtained such gratifying results, and which seemed to fulfil all that even the most fastidious photographer could desire. The plates, he believed, were prepared in Scotland, and being exposed in France, and developed—some of them probably months afterwards—in Scotland, seemed to him to betoken their excellence, whilst it did great credit to the manipulative skill of Mr. McGhie, who was bound to rise high in his profession, and for whom he would augur a successful future. His perseverance he would seek to commend. His artistic ability and chemical skill enabled him to put, all he undertook to the best possible advantage. The proceedings then terminated.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The usual monthly meeting of the Society took place at the Memorial Hall, Albert Square, 13th instant. Mr. CHARLES ADIN (President) in the chair.

The minutes of a previous meeting were read and confirmed, and Mr. Charles Harris was duly elected a member of the Society.

The SECRETARY called attention to one very important matter in connection with the Society—that of members paying their subscriptions now in arrears. Some members (he said) came very regularly, and enjoyed their tea, and took part in the proceedings, but quite forgot to pay their subscriptions, even though they had not done so for two years or more.

The CHAIRMAN then read the business card of a Manchester photographer, and sympathised with those professional gentlemen present, seeing the very strong competition they were to endure. The card read as follows:—

"Mr. —, professor of singing and music, miniature painter, phrenologist, taxidermist, mesmerist, and photographer, Manchester.

"Mr. — respectfully announces to the inhabitants of Harpurhey and neighbourhood, that he has erected a first-class studio, for the production of the best styles in every branch of the art of photography. Mr. — calls special attention to his new Opalotype portraits, which, for beauty and delicacy of detail, are equal to ivory miniatures. Wedding and other groups taken at parties private residences. Horses, dogs, and other favourites photographed. Cartes-de-visite from 5s. per dozen copied to life-size. Old faded Daguerreotype portraits renovated and restored to their original beauty—having had upwards of thirty years' experience as an artist. The state of the weather is of no importance. Family residences, machinery, &c., photographed on the shortest notice. Families photographed at their own residences, without extra charge. A portrait club, which enables every one to obtain a correct portrait, coloured in oil, in gilt frame complete, and a dozen cartes-de-visite for the low sum of £1 10s., payable at 1s. per week.

"Busses from — run every five minutes, and alight passengers at the door. Evening parties attended for mosmoric entertainments. Characters correctly delineated. P.S.—Birds and animals preserved and stuffed on the most approved and scientific principles. Lessons in singing, with pianoforte accompaniment. Picture frames of every description made to order.

"A respectable young lady or youth wanted, as an apprentice: premium required, nevertheless.

"Mr. — wishes to correspond with a young or middle aged lady, must be fond children and music, with a view to matrimony. A widow lady with children not objected. He is 40 years of age, tolerably good looking, likes a glass of beer, and has a particular wish to live 36 years longer, then go home and see his mother, where he will sing

"God save the Queen and
John Brown, the piper."

Photography by artificial light was the next subject before the meeting.

Mr. BROTHES had brought a very simple hand-lamp (or reflector) in which magnesium wire was burned, and Mr. Harrison-

Garside had arranged in the adjoining room the Moule's lamp, and a new chimney he had made for it.

After some discussion, and explanations from Mr. Brothers on the magnesium apparatus, a plate was exposed upon the President by Mr. Schofield and also by the Secretary, the illuminating being conducted by Mr. Brothers. The members then retired to the adjoining room, where they had an opportunity of seeing the Moule lamp in operation, and two plates were exposed by the light, the results to be communicated at the next meeting.

Mr. SCHOFIELD exhibited a large gas burner by Mr. Sugg, of London. This, owing to a half-inch gas pipe being required, was unable to be tried at the meeting; but at the invitation of Mr. Schofield a few members afterwards inspected its capabilities, which were, for ordinary gas, really astonishing.

A vote of thanks was passed to Mr. Brothers, Mr. Garside, and other gentlemen, and the meeting terminated.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday next, April 1st, at the Gallery, Pall Mall East, when the adjourned discussion on Mr. C. Bennett's paper, "On the Gelatine Emulsion Process," will be resumed; some samples of cotton, &c., for making pyroxyline will be exhibited; and Col. Wootley will show some pyroxyline washed in ammonia.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will take place on Thursday next, April 3rd, at eight o'clock, in the rooms of the Society of Arts, Adelphi, when Mr. T. Archor Clarke will read a paper on "Artificial Light." Mr. A. Brittlbank will also read one on "How to Take a Negative by Artificial Light for 1½d."

HEIGHWAY'S PRACTICAL PORTRAIT PHOTOGRAPHY.—This excellent little manual has recently received a very decided, although peculiar, compliment in America, where it is charged, in the *Philadelphia Photographer*, with having copied "language, chemistry, and errors," an American manual. No one who is familiar with Mr. Heighway's fluent and pleasant style of writing, as found in our pages, would dream that he could find it necessary to copy the language of another man; and as for the matter in a manual of photography, it is as much common property as the multiplication table, and must as inevitably be used over and over again as are the letters of the alphabet. But the charge of copying is manifestly a high compliment. It practically says: "This is good; good enough to be our own!" Mr. Heighway, of course, indignantly denies that there is a shadow of foundation for the charge. But having lived in America, he is manifestly hurt that such a charge should be made by some whom he has known, and who have known him.

MR. J. T. TAYLOR.—Mr. Fitzgibbon, Editor of the *St. Louis Practical Photographer*, speaks of meeting Mr. Taylor in New York, and is much pleased with his open free manner; but he does not think hopefully of the business project. He says:—"We understand he comes to New York as manager of A. and G. Taylor (by their card) Photographers to the Queen and the Prince and Princess of Wales, 763 Broadway, N. Y.; 814 Arch Street, Philadelphia, and 535 Washington Street, Boston. The sign is very attractive on Broadway, but it won't take in this country. The firm proposes to make a specialty of large head work, 8 by 10, 10 by 12, and 11 by 14, finished in water colours, neatly framed, and sold at reasonable rates. We are afraid they will find this style, and almost every other coloured cheap picture, have already had their day in this country. If they are successful—which we sincerely hope they may be—we shall be surprised and astonished. They have fitted up very fine rooms in New York, and gone to considerable expense, not only there, but at their branches in Boston, Philadelphia, and Chicago. They brought over some seventeen assistants, who are up in their style of work and the way they do business. We hope our brethren will give them a cordial welcome."

To Correspondents.

JOHN LEWIS.—We have frequently advised in relation to gold recovered from residues of toning baths. Throw down with sulphate of iron, wash black deposit with dilute sulphuric acid to remove traces of iron, rinse well, and dissolve by means of aqua regia, neutralize, and use.

AN OLD PHOTOGRAPHER.—We cannot state with certainty the precise date at which Mr. Beard, or anyone else, first produced Daguerreotype portraits in London. Can any of our readers supply the information? It was, we believe, in the year 1840.

G. D. MACDOUGALD.—Our correspondent asks a question identical with many we receive at present; to which, however, we cannot give an answer which will be deemed satisfactory by the querists. The enquiry is for the best formula for the gelatine emulsion process. We have published all that has been made known on the process, but we cannot decide what is best. Nor can we repeat or epitomize processes which we have already given in full. Our last volume has many articles on the subject. Take the process as described on the second page of that volume, where it is clearly, fully, and simply described.

GEORGE WEBBER, JUN.—We cannot tell you where to procure flock paper of a specific tint; but we imagine that it may easily be found by a little search amongst the shops of paper-hangers. We have seen such tints in the shops of high-class paper-hangers.

CITRIC ACID.—A correspondent, who signs no name, complains that he has accidentally put citric acid into his negative bath, and wishes to know how to remove it. Let him add an alkali, caustic potash by choice, or ammonia, until no more precipitate falls; carefully filter, and then expose his solution to sunlight for a time, and then try it. If it still work unsatisfactorily, use it for printing.

A. MILLER.—For the relation between the various stops of any special lens or series of lenses, you should enquire of the maker. The special information you require, you will find in two articles on "Stops," by Mr. Dallmeyer, in our YEAR-BOOKS for 1876 and 1877.

SOUTH DEVON.—The surface of the picture should be next the polished surface of the press.

THE LUXOGRAPH.—Messrs. Alder and Clarke write to correct inaccuracies in Dr. Drinkwater's paper on artificial light. They especially complain of the statement that the Luxograph is the invention of Mr. Lombardi. They are probably aware that statements to that effect have appeared in the daily press; but the true facts of the case have so definitely appeared in our pages, that there is little danger of misapprehension. Letters reaching us on the day on which we go to press cannot receive attention the same week.

K. H. C. O₃.—You may safely adopt the plan you propose, or throw down with carbonate of soda, and redissolve with nitric acid; or boil down, crystallize, wash, and recrystallize. Or if you doubt, send to a refiner.

LUX.—There are no definite rules for the valuation of photographic businesses. None can be laid down for the valuation of negatives, so much depends on the character of the connection. A general rule with indefinite businesses is based on income. Two or three years' value of net profits sometimes forms the basis of a valuation. We have known a business similar to that you describe offered for £500, and thought it exceedingly moderate. We have been called upon several times to assist professionally in valuations, and have always done so with fresh reluctance, the basis of such valuation being so uncertain. We cannot, in these columns, advise on commercial questions.

FRANK DORE.—The method is given in the gentleman's own words. There is no necessary error. The reactions are very similar to those you describe.

G. L. HOWIE.—We will write to you shortly.

R. G. writes to confirm our remarks in a recent leader on keeping sensitive paper. He finds the carbonate of soda soaked paper answer satisfactorily. Thanks.

AMATEUR.—Yes; the precipitate will fall to the bottom, and the clear liquid may be decanted off; or you may remove the deposit, which is citrate of silver, by filtration.

LITTLE PHOTO.—We are glad to learn that it was not our old correspondent who was in such bad case. It was wrong and foolish of another person to assume a *nom de plume* which was already appropriated. We agree with your general remarks.

A. A. C.—The part played by nitrate of uranium in dry plates is not well understood. 2. Either brown or slate colour will do for a plain background, one as well as the other. Whether you can dye a large piece of calico with Judson's dyes, or not, we cannot tell. Try a small piece first. We fancy that weak coffee would give you a good brown.

W. HALL.—It is fairly within the competence of anyone to refrain from using novelties, but is scarcely fair to revile those who are enterprising enough to experiment. It is to such men that photography owes its present position, or even its existence, and many professional photographers their means of living. We cannot give you facility for charging many of the best men connected with the art with being "gullible." Our space is too valuable for mere invective.

VINCENT HATCH, R. V. HARNAN, and WILLIAM GREEN in our next.

Several correspondents in our next.

The Photographic News, April 4, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHIC TRANSPARENCIES UPON THE SCREEN—THE HELIOSTAT AS AN IMPLEMENT OF WARFARE.

Photographic Transparencies upon the Screen.—We are glad to see that Mr. J. Thomson has made some further use of his photographs of Cyprus, beyond putting them into a book. No doubt his recently-published volume, *Through Cyprus with the Camera*, amply fulfils its design, and gives the peruser thereof a far more realistic idea of the newly-acquired British possession than any number of closely-written pages. The plates, as one passes from one to another, put the characteristics of the island vividly before you, and it is only necessary to turn the page in order to flit pleasantly from place to place. A street in Larnaca is followed by the fir-clad slopes of Mount Olympus, while groups of natives shows the costume of the islanders has scarcely changed for centuries. What may be termed Old Cyprus and New Cyprus are depicted by one picture of an antique mosque crumbling to ruin, and by another in which some Royal Engineers in smart uniforms are carrying on the work of surveying, &c. Mr. Thomson's prints, therefore, are admirably suited for the illustration of a book on Cyprus intended to bring us face to face with that island; but they convey a better idea still of reality when employed as transparencies, and thrown upon a huge screen by the aid of a powerful lamp. It is surprising how much there is in a photograph when viewed in this manner. Microscopic details which the eye fails to perceive, or at any rate to regard with any importance, are brought out in a most striking fashion, and, indeed, the original scene is reproduced as truthfully as it is possible by photography. And how nearly to nature scenes can be rendered, only those who have seen good photographs shown in this way know. We remember some years ago seeing a little stereo picture by William England thrown upon the huge screen in the Polytechnic. It was a photograph of the square at Rouen, in the centre of which was a statue of Joan of Arc. We are not quite sure of the dimensions of the Polytechnic screen, but it is probably forty or fifty feet high, and the photograph in question was made to cover the greater part of it. So sharp and distinct was the square, and so thoroughly illuminated, we remember, that the actual spot seemed before one's eyes. We can well imagine, therefore, that Mr. Thomson's Cyprus photographs, which were recently employed in a lecture on the Island and its People, by that gentleman, given in aid of Dreadnought Hospital, conveyed a more vivid impression to stay-at-homes than any other means could give them. There is nothing more delightful, indeed, than sitting down comfortably, and watching scene after scene of this kind put before you. And yet we in this country have made little use of photographs enlarged and exhibited in this fashion, except, perhaps, in a semi-private manner. Now in Paris such things are far more appreciated. For some years the Abbe' Moigno organised public lectures or entertainments in Paris at the *Salles de Progres*, in which camera pictures were much utilised. He superseded in a measure the employment of a microscope, which is always difficult to use in classes or large assemblies, even when one has to do with people who are not entirely ignorant of the instrument. The use of costly diagrams was also obviated, for photographs of small objects could be enlarged to any extent. You still had the real thing before you instead of an exaggerated drawing of it. When the Paris Photographic Society holds its annual exhibition, good use again is made of transparencies of a photographic nature in this way. On payment of a franc are secured not only the right of entrée to the exhibition, but twice a day there was a display of photographs upon a screen by the help of the oxy-hydrogen lamp. We passed a very pleasant half hour on one of these occasions, and were startled at the effect produced by some of Léon and Levy's clever instantaneous views. A picture of

a three-decker being towed into Brest harbour was marvellous. To be looking out at sea at the end of the Jetty watching the waves breaking, and almost feeling the rough wind against one's face, as the majestic man-of-war comes slowly on, with yards taut and pennant streaming, and to see this all the time you are comfortably ensconced in a warm room, upon softly cushioned seats, is no small enjoyment. A stereoscope is very well, but one cannot deny that after a dozen slides the bridge of the nose and one's forehead begin to ache. In the matter of the screen, however, if the pictures are skilfully thrown, the entertainment is one of unmixed delight. A glacier which, under ordinary circumstances, would, at the least, cost £10 and a week of travel to view, may here be seen without the trouble of turning one's head. The pinnacles of ice, the snowy crystals, the soft undulating fields of white extending in every direction, are at our feet, and in the foreground are the steep rocky moraine and huge pillars of translucent matter that is melting away under our eyes. Another transparency shows us a tearing waterfall, the splashing foam falling among the black fir trees on either side, and sending up a column of white mist and vapour, that you almost feel bedewing your face. The next picture is a well-known inn in Chamounix, the big overgrown diligence that goes to Geneva standing under the long wooden balcony in front of the house, while the landlord and half a dozen picturesque guides are posed at the entrance; above, almost overhanging the houses, is the Montauvert, the Mer de Glace, and other rather hackneyed resorts. As we said before, those who have not seen good photographs skilfully thrown upon a screen in this fashion, know not how charming and artistic they really appear, and it is a pity that this form of entertainment is not more frequently to be met with in this country.

The Heliostat as an Implement of Warfare.—The heliostat has become an implement of war. Photographers and astronomers are henceforth not alone to monopolise the moving mirror, for generals in the field are to be supplied with the instrument for signalling purposes. The heliostat, as our readers know, is a mirror furnished with a clock-work arrangement which permits the reflecting surface, so to speak, to follow the sun. In this way, one station can steadily reflect a ray to another the whole day long, or, at any rate, as long as the sun is visible. All that is necessary is to observe this ray at times, and the appearance and disappearance of the bright spot furnish a means of signalling to a distance. At night time, either a colza-lamp of exceptional brightness is employed, or else a mixture of powdered magnesium and resin—artificial light; photographers, please note!—which is puffed into a spirit flame. The spirit flame is naturally enough invisible at a distance of some miles, but the vivid brightness momentarily produced by the magnesium and resin does not fail to make itself seen for many miles. Signals are exchanged in this way, in the same manner as with the heliostat, but of course the ray from the latter is more intense. With properly adjusted stations, sun signals can be seen, without difficulty, at a distance of twenty miles and more. Up the Khyber Pass to Jelladabad the signalling just now is mostly done by the heliostat, and half a dozen of these valuable instruments have been recently despatched to the Cape. It is one of the most ingenious systems of signalling devised, but, obviously, sunshine is necessary for working it.

Correspondence.

EMULSION PLATES IN THE STUDIO.

DEAR SIR,—I have been much amused, lately, at the importance some writers in the News seem to attach to priority in putting aside our old friend the silver bath in favour of dry plates for studio work, and the eagerness with which they claim for themselves the honour of having been the first to do so. Now, if this is really an important point,

I must score in advance of those claims I have seen published, as, so far as I can learn, from any information I have been able to obtain, I was the first to abandon the silver bath.

I began using Swan's plates in April last year, and since the first week in June I have used them exclusively for both portraits in the studio and outside groups and views, with the exception of one or two short intervals, when, owing to the enormous demand, I could not obtain sufficient supplies, and was most unwillingly obliged to employ the wet collodion process.

Even for enlargements up to 18 by 15 (I seldom do larger than this at home) I have given up the bath, and use emulsion, notwithstanding the fact that I have gallons of collodion and bath still on hand, as I can obtain results far superior to what I did with the old process after nineteen years' practice.

I believe I was also the first to cure blisters and frilling by the use of alum. I handed my method of using it to Mr. Swan, who was so much pleased that he printed it *verbatim* on an extra slip of paper, and for some months it was enclosed with the instructions in each packet of plates, until, owing to an improvement in the preparation of the plates, the precaution was considered unnecessary. Mr. Ferranti quotes the method in his article last week. I may state that I always employ the ferrous oxalate developer.

Your correspondent "Gratefully," in last week's issue, may find it useful to know that a very fruitful cause of blisters and frilling, is using the hypo fixing bath *too strong*. It must not be stronger than four ounces to the pint; and I use it much weaker than this.

I find it a safe rule to weaken the solution, if the plate does not appear *smooth* for a moment before greasy lines come over it, after having been plunged five times into the fixing bath; this alone, or in conjunction with the alum treatment, I feel sure will put an end to his troubles.—I remain, yours truly,

WILLIAM GREEN.

Berwick on Tweed, 20th March.

[The question of priority in using is, as our correspondent suggests, not of much importance. The date mentioned is about the same time that Mr. Ferranti commenced using gelatine plates in the studio. A card before us, dated 1868, announces "night photography" at the studio of Mr. J. H. Fitzgibbon, in St. Louis.—Ed.]

ARTIFICIAL LIGHTING, AND MR. HARMAN'S CITY MAN.

SIR,—Relative to Mr. Harman's brief pointed allusions tending to pervert the tenor and meaning of my remarks on the all-absorbing subject of artificial lighting as applied directly to portraiture, possibly, I may not have been sufficiently explicit. From Mr. Harman's standpoint all looks well enough, but from mine the aspect is somewhat different. There are two sides to most things, and, unfortunately for the lovers of artificial lighting, the human face is no exception. Artificial lighting and Mr. Harman's remarks thereon apply well to the "trade" branch of the profession, likewise for enlarging and copying when occasion requires. It may also be serviceable as an aid to dark daylight operating (to use an apparently Hibernian expression). I have nothing whatever to say against it; on the contrary, I am greatly in favour of it, decently and judiciously applied. All I would wish to avoid is this detestable "night business" into which there would seem to be a tendency to drift. In establishing such, we should be doing what drapers' and others "early closing" trade associations are doing their utmost to suppress.

Even granting artificial light equals the sun's light in quality (which, to my mind, appears about as impossible as photographing in natural colours), why should we thus force the public to patronize us at night, when, *if there was*

no such institution, people wishing to be photographed would find or make time to sit as they do now?

I would like Mr. Harman, or anyone else, to show clearly how, or by what means, photographers (more especially those doing a respectable high-class business) will benefit themselves and the public generally by the introduction of such a system. I confess I fail to see one single advantage. I see many disadvantages; not among the least of them, we should be at much greater expense, we should turn out inferior work at higher prices, and we should have no chance of breathing the fresh air, which I hold is most requisite and necessary in such a business as ours.

I do not see why we should expect to have any more sitters (after the novelty rush had subsided), and, in my opinion, the class of people who would most generally patronize night studios are such as would do the first-class photographer no credit, nor tend to raise him in his own or the public's estimation.

Artificial lighting in its present state for high class and art portraiture (to which my "objections" apply) can find favour with very few of our best photographers. The reasons surely are obvious; nevertheless, I will briefly sum them up as follows, omitting altogether the "sentimental" (on which in my previous letter, perhaps, I dwelt too strongly, at any rate, for Mr. Harman's taste).

1. It does not give round soft brilliant pictures equal to daylight.
2. It does not tend to improve the expression or steady the nervous.
3. It compels you to advance your prices and increase your expenses.
4. It compels you to employ more hands at higher wages.
5. It compels you to be there to look after them and the "machinery."
6. It compels you to turn out two distinct classes of work.

I say nothing against "night studios" as *separate* institutions, and *altogether apart* from our ordinary respectable daylight businesses (just as the photographic booths at a fair, for in much the same light should I regard them), but I do think it would be a very serious mistake for photographers generally to tack on a night studio to their present legitimate work; in fact, they cannot see their way to do so whose aim it is to turn out first-class work regardless of the silly whims of certain sitters (only too well known to most of us) who "really can't come again."

It may be argued, relative to the "restless subjects" (obvious reasons No. 2), that the brevity of exposure counteracts all difficulty as regards their "moving" or looking like "wild cats;" but I say not so; a sitter possessed of an inclination to move can do a great deal of "work" in ten seconds—at least, I have found it so under the most favourable daylight conditions. I contend that a rapid dry plate on the dulllest day in winter would have more chance in securing a generally successful picture of such subjects.

Among these latter I class Mr. Harman's "City Man." City men in general, if they take my advice, will do well to avoid the "blue fire" of a night studio—the extremely irritable gentleman (so graphically described by Mr. Harman) in particular, if he really is anxious to appear to the best advantage on his devoted partner's birthday. "Blue fire" on the distant stage of a theatre, and a "stroll by moonlight" enjoyed at a still great distance from the source of illumination, are slightly different things, in my humble opinion, to having a flare-up of Chinese fireworks going on almost under your very nose when sitting for a portrait.

Are such conditions, may I ask, favourable to the securing of a satisfactory likeness—even of the "City Man" class of which Mr. Harman has made (as he thinks) so ad-

mirable an example? Moreover, whilst viewing pantomimic blue lights at a theatre, or gazing on the face of his (or some other fellow's) "beloved" by moonlight, our City gent. is permitted to make the ugliest and most outrageous faces he pleases; but under photographic fire, as above described, the conditions are different, and he is expected to look calm and collected; and immediately preceding the firing of the powder he is earnestly entreated to "look pleasant" and "keep quite still."

Referring to the sentence, "Photographers have enough to do," &c, Mr. Harman again ingeniously endeavours to pervert the true meaning of my text. Does Mr. Harman seriously think I was alluding to the past four months? If so, he must deem me either a miraculously lucky photographer, or a true born idiot.

It would indeed be a treat to hear of (much more to see) a photographer who has been busy during this past painfully depressing period; but we must not forget the future, whilst dwelling so greatly on the past and present, and to which (in contrast to Mr. Harman's remarks on this point) I would direct his attention.

What about the four months from July to October, and would Mr. Harman then consider his night business a desirable accessory? Would he (after a hard day's work, which, at that season of the year, all good photographers are supposed to enjoy) like to turn into his "night shop," and work away till goodness knows what time? I should say his night *shirt* would (or should) prove the stronger attraction of the two, or Mr. Harman possess a sturdier constitution than most of us. For Mr. Harman, and all advocates of the night work system, must remember they cannot open and shut up shop at pleasure to suit their own fancy and convenience. A night business once set going must be continued without cessation throughout the year, or it will prove worse than a failure; and the question is, will it pay in the long run, even second and third rate photographers? I think not. Doubtless there will be a "rush" just at first, while the novelty is on, but when that has subsided the discriminating public will not be slow to appreciate the fact that a dull day is better than a light night on which to have their "phizzogs" most advantageously portrayed.

I would wish it to be distinctly understood that I regret the introduction of artificial lighting, as directly applied to portraiture, *only so far as this night work* is concerned, and by its possibly general adoption all might have to "follow suit," when there is no necessity for such an innovation. I regard it as a good "hit" for those specially concerned and interested in the manufacture of these interesting instruments (the variation in the cost of which is rather amusing, not to say significant), and, as I before said, used judiciously—not abused—they should prove in the hands of the skilled photographer a great boon; but I must most certainly take exception to Mr. Harman's theory of revenging ourselves on the past exceptionally bad weather and general trade depression (the effects of which, as a matter of course, we have all felt) in the manner he sets forth.

In London, and other large cities, we know, there is a call for something "catching" (if I may be allowed the term). When "uncertain" sitters come, they must be taken somehow, and so, of course, they should be; but even in such cases I consider the general advantages are on the side of rapid dry plates in a dull light. But in smaller towns, such "slips" are not to be so feared, and by giving your visitors an appointment card to fill up and take with them, you are pretty certain to secure their return on a more favourable occasion; or, if you have any reason to doubt them, secure a deposit by showing them a "positive." You will find that a *positive* remedy for this complaint. There are more ways than one of doing business and hooking a customer, and any way is better than by turning out inferior work, though, by reason of the sensa-

tional character of its "machinery," the "artist" may derive benefit for a season.

I could say much more, so strongly do I feel on the subject to which my remarks directly point; but I forbear to trespass further on your indulgence and valuable space.

—Faithfully yours,

VINCENT HATCH,

Huddersfield, March 25th.

ARTIFICIAL LIGHTING.

SIR,—I have no wish to be drawn into a controversy on the subject of artificial lighting, but, as "Operator's" letter in your last issue provokes a reply, I will trespass on your valuable space as little as possible.

I think your own remarks in last week's article are sufficient answer to "Operator's" argument, and justify the practice of artificial lighting; but I would supplement them by saying that my paper was not on behalf of the photographer "whose business and income are sufficient," nor to the injury of operators and assistants, but for hundreds of struggling photographers who have now to compete with the "enterprising men" who have already successfully introduced artificial lighting in their business.

When so many good houses and eminent firms adopt night, and we see their productions circulated amongst us, it is time to act on the defensive, and by introducing an efficient instrument and process that is within the reach of all, I believe I am not acting in opposition to the interests of either employer or employes.

In conclusion, as "Operator" takes a ludicrous view of my city gentleman, I may say that I certainly do "know him best;" and *if* the hours and habits of the British workmen are such as "Operator" describes (he possibly has a better opportunity than myself of knowing what is most congenial), I shall be glad to leave him in "Operator's" society. —I am, sir, yours truly,

R. V. HARMAN.

P.S.—After a declamatory letter, "Operator" asks me to publish my formula for the benefit of himself and others. My original formula has already been published, but I have now discarded it for one infinitely superior, which lights easily and is impervious to moisture. As "Operator" is anxious to try it, he may be equally anxious to buy it, and he will find the price in another column.

FRENCH CORRESPONDENCE.*

Recent Inventions.—As we are on the subject of inventions, and more especially as we always consider it a duty to aid the efforts of inventors by making known to our readers any novel processes that are of a kind to interest them, we take the opportunity of recording the success of a new paper for reproducing by photography plans, drawings, sections, maps, &c. This paper, called from its inventor, the *Papier Artiques*, competes with that of M. Pellet, so far as regards the services they can both render to manufacturing industry. The invention comes to us from Bordeaux. By placing the paper beneath the copy to be reproduced, and submitting it for a few seconds to the action of light, a negative is obtained with white lines on a black ground. The paper is then sensitized with bichromate immersed in a bath of water, and thoroughly washed, when prints equal to engravings or lithographs are produced with black lines on a white ground. For engineers, and all who require to obtain a large number of copies of the same drawing, this process possesses very great advantages; but it has, unfortunately, one grave fault, and that is that it is excessively costly. The price of the paper at the present time is 600 francs the ream, or 35 francs the quire; in order that it may be able to take the place to which it is entitled, and to make its way in the industrial world, the inventor must really make up his mind

* Continued from page 151.

to lower his terms. Before the *Papier Artigues* can become popular, it must be in a position to contend advantageously with other papers answering the same purpose. There is no doubt that if it can be brought within the requirements of those possessed of moderate means, there will be a large demand for it. Another model invention, deserving to be noticed, though it has no other relation with photography than that of being the reproduction of an image, consists in obtaining copies by means of an apparatus called the *Chromographe*. A copy is made by writing or drawing with a special ink; this is applied to a flat sheet of a kind of gelatinous paste surrounded by a zinc frame. By lightly rubbing the back of the paper, a negative is immediately produced on the paste; then by simple friction with the fingers a large, though limited, number of proofs can be produced. The copies are blue or red according to the colour of the ink with which the original was written. Ingenious as the above described process will be found to be, the searchers for new methods are more ingenious still. Scarcely has the *chromographe* been for a few weeks before the public of Paris (the inventor, who is working out his invention here, hails from Vienna), than another manufacturer brings out a similar process, and advertises it under the title of *Polychrome-Autographic*. The purchaser is supplied merely with a stick of a substance consisting of an aniline base and tallow; the stick, which is soft, and resembles *cosmetique* in appearance, must be rubbed over a flat surface, when it will leave a layer of the substance. To this layer is applied a sheet of paper, on which we can write or draw with any pointed body—such as a pencil, a piece of wood, an awl, or even a pin, provided only that it be hard enough to make a dent in the layer. On the other side of the sheet of paper will be found an inverted tracing of the writing. Over this negative is now laid a piece of wetted paper, and a gentle pressure applied, when a perfect impression of the copy is obtained. By this means, from the same negative, up to fifty excellent prints may be drawn in either a blue or violet colour. It would appear, therefore, that the old copying processes have seen their day, more especially as these two new methods are of marvellous cheapness.

COMPETITION OF THE BELGIAN PHOTOGRAPHIC ASSOCIATION.

We have received from the Section of Liège of the Belgian Photographic Association a circular, of which we append a translation.

Liège, 26th Feb., 1879.

SIR,—We have the honour to inform you that the Section of Liège of the Belgian Photographic Association has received from a gentleman, who desires that his name may not be published, the sum of five hundred francs to be offered as a prize for the best emulsion process. The donor has laid down the following conditions for the competition:—

1st. The regulations of the competition shall be drawn up by the Section of Liège.

2nd. It shall be open to all Belgian subjects, and to foreigners who are members of the Belgian Photographic Association.

3rd. Any emulsion, whether washed or not, with or without preservative, will be permitted to compete. The committee of judges shall decide without appeal on the excellence of the process submitted for competition.

4th. The cost of an emulsion when ready for use is not to exceed two francs per cub. centim.

Though fully recognizing the value of the Warnerke process, to which the prize of the Association was awarded in 1878, the Section consider that all the expectations that might with justice be formed of the capabilities of such a process have not been fully realized, and more especially, that the manipulations required in working it are capable of being simplified. They believe that a competition of the kind now proposed to them cannot but have a beneficial effect in introducing improvements; they therefore accept with gratitude the task of organizing the

award of the noble prize that has been placed at their disposal. In the following eight paragraphs are contained the regulations that they have drawn up for the competition:—

1. The prize for the best emulsion process is offered under the above described conditions.

2. Every emulsion submitted for the competition must approach as near as possible to the wet collodion process as regards rapidity of working and final result.

3. The committee of judges is to be composed of seven members; they will, in accordance with the wishes of the donor of the prize, hold their meetings at Liège.

4. Each competitor must send in twelve plates, 18 by 13 centim., ready for use; also three flasks of his emulsion holding one hundred cub. centim., as well as sufficient preservative, if one be employed. He must forward, with the above, a detailed description of his process marked with some cipher or device, and a sealed envelope bearing on the outside the same cipher or device, and containing the name and address of the sender. Any competitor who makes known his name will be excluded.

5. All these articles must be sent to the Secretary of the Section, M. Albert Damry, 37, Mont-Saint-Martin, Liège, before the 1st July, 1879.

6. If none of the competitors submit processes fully complying with the requirements, it is in the power of the judges to award a part of the prize to one or more processes that fulfil the larger number of the conditions.

7. The result of the competition will be declared at a meeting of the Section during the month of January, 1880.

8. The judges may cause to be published every process, whether printed or not, that is submitted to them.

Should you require any further information, we shall esteem it a favour if you will address yourself to one of the undersigned, either directly, or, in case you wish your name not to be known, through an agent.

We have the honour to be, sir, your most obedient servants,
L. L. DE KONINCK, *President*.
R. DE SELTS, *Vice-President*.
A. DAMRY, *Secretary*.

PRIZE COMPETITIONS OF THE PHOTOGRAPHIC SOCIETY OF VIENNA.

The following are the arrangements for the prize competition offered by the Photographic Society of Vienna in the present year. It will be seen that the list of medals is divided into two competitions, the terms of which are slightly different. The first list contains the medals provided out of the Voigtländer fund, the second those offered by the Society itself.

1.—THE VOIGTLÄNDER MEDALS.

1. A *gold medal*, value 1,500 francs. For a method of increasing the sensitiveness of wet plates.

2. A *gold medal*, value 1,500 francs. For the best dry process as regards certainty and sensitiveness.

3. A *gold medal*, value 500 francs. For a collection of studies by the gelatine emulsion process.

4. A *silver medal*. For a collection of studies of natural objects.

5. A *silver medal*. For a collection of instantaneous stereoscopic photographs.

6. A *silver medal*. For a collection of lantern slides for illustrating instruction in natural science, art, and technology.

7. A *gold medal*, value 500 francs—also silver and bronze medals. For scientific treatises, inventions, and improvements, first published either at the meetings of the Society, or in the Society's journal, the *Photographische Correspondenz*; also for meritorious photographic works.

All the above medals are only open for competition to members of the Photographic Society of Vienna.

Works submitted for competition for the medals Nos. 3, 4, 5, 6, must be sent in before the 1st October, 1879; those for the medals Nos. 1 and 2 before the 1st May, 1880.

The medals will be awarded on the report of a committee appointed to examine the works submitted for competition, and the awards of the medals Nos. 3, 4, 5, and 6 will be declared at the General Meeting of the Society in December, 1879; those of the medals Nos. 1 and 2 at the General Meeting in December, 1880.

II.—THE SOCIETY'S MEDALS.

1. *A gold medal*, value 1,500 francs. For the production by photography of printing plates in high and low relief, so as to give half-tones.
2. *A gold medal*, value 1,500 francs. For an essay on pyroxyline and collodion.
3. *A gold medal*, value 500 francs. For profound researches on asphalt.
4. *A silver medal*. For genre pictures.
5. *A silver medal*. For carbon prints taken in Austro-Hungary.
6. *A silver medal*. For a collection of photographs of ancient monuments.
7. *A silver medal*. For a collection of ethnographical studies.
8. *A silver medal*. For a collection of anthropological studies.

Works submitted for competition for these medals must be sent, carriage paid, to the President of the Photographic Society of Vienna (Dr. E. Hornig, K. K. Regierungsrath, 9, Hauptstrasse, Wien, III), before the 1st October, 1879.

The prizes will be awarded by the committee appointed to award the Voigtländer medals, and their decisions will be declared at the General Meeting of the Society in January, 1880.

In both the competitions, the works sent in must be marked with a cypher or device, and accompanied by a sealed envelope containing the name of the competitor, and bearing on the outside the same cypher or device. In no case will an envelope be opened unless the corresponding work has a prize adjudged to it.

All the works submitted for competition in the form of pictures or studies will be publicly exhibited.

The Photographic Society reserves to itself the right of awarding prizes of less value to works which do not comply in all respects with the requirements of the above programme.

Full particulars and details can be obtained of the President of the Society, whose address is given above; or of the Secretary, Herr F. Luckhardt, K.K. Hofphotograph, 18, Taborstrasse, Wien, II.

SOME REMARKS ON FINANCE.

BY F. A. BRIDGE.*

MANY years ago (I think in 1791) Mr. Holcroft wrote an excellent comedy, entitled *The Road to Ruin*, in one part of which, in consequence of the reckless behaviour of his son, "Old Dornton" (the father) is made to say:—"Oh! who would be a father!" Towards the end of the fifth act, however, things change so much for the better, and the conduct of the son comes out in such a satisfactory manner, that his father completely reverses his former sentence, and exclaims—"Oh! who would *not* be a father!" Now, when I first undertook the responsibilities of Treasurer to the South London Photographic Society, and found we were £9 on the wrong side to begin with, I thought the position would not be a very comfortable one; but worse remained behind, and instead of being £9, the deficiency was nearer £16. I then felt very much inclined to paraphrase Old Dornton's speech, and exclaim—"Oh! who would be a *Treasurer!*" Well, gentlemen, I must say I was very sorry to find that the officers of our Society, in the fulness of their artistic hearts, had allowed so many subscriptions to fall into arrear; but after a careful rearrangement of the books I found many of our best photographers had allowed themselves to occupy the distinguished but scarcely creditable position of defaulters, and that we had nearly twenty members who had not paid for more than three years! I began then to wonder whether the attainment of artistic excellence really blunted the feelings against paying debts and honourably carrying out arrangements voluntarily undertaken. Letters have been written to these defaulting gentlemen over and over again, and, as I informed the committee at our last meeting, I had

even made a final appeal to them, enclosing a stamped envelope, but with very little success. I am sure, therefore, the members will regret with me that so many of their fellow-workers and members of the photographic profession—some of them whose names are as "household words" with us all—have allowed their names for such a reason to be removed from the books of our Society, because there can be no doubt we should have thought much better of them personally, and applauded their productions none the less heartily, had they paid their subscriptions with regularity, or, when they felt disinclined to do so, had honourably resigned. It may be argued that these gentlemen rarely visit us. This is true; but I do not know whether this is any excuse for some members (not many, fortunately) who continue their attendance at our meetings with almost unerring regularity, and never pay at all! Now we are at all times ready and glad to welcome to our meetings those connected with our art, no matter where they come from; but I think if people whose names are on our hooks as members attend our gatherings, we have, as it were, a double right to expect they will pay their subscriptions. It might surprise a few (or perhaps many) of our members to hear the excuses made by some of those to whom application has been made for arrears. One gentleman, for instance, excuses himself for not having paid for three years on the ground that he has not received any presentation prints during that period, forgetting that not having paid his subscription he would not have been entitled to them had we been able to arrange for them. Again, if members do not pay their subscriptions, I should like to know where they think the money is to come from to provide presentation prints. Another says he has left the Society, with several other members, because of the great favouritism shown to some few. Well, gentlemen, favouritism may exist, but if it do, it is unknown to me. It has always seemed to me that all a gentleman has to do to entitle him to take part or give his opinion at any of our ordinary meetings is to be present. I never remember our worthy President, or the chairman for the evening, or any member objecting to anyone stating their views or experience, whoever they might be, and we have always been glad for anyone to do so, feeling sure that the friendly and social intercourse of late years among photographers in such societies as our own has very greatly tended to do away with many of the little petty jealousies that existed in our profession years ago. However, gentlemen, I will not take up your time with any more remarks of this kind, but proceed to business.

When December, 1878, came, and I was called upon to surrender my first balance sheet, I asked to be allowed to wait a month or two, in the hope that I should be able, during that time, to impress upon the defaulting members the desirability of paying up their arrears. I have succeeded in getting in seventy-five subscriptions during the past year, and as the number of paying members on our books was (up to December) only about fifty, you will see to what extent I have prevailed upon our defaulting members. Each meeting this year has, I am happy to say, increased our number, and I hope it will continue to be so. Up to the end of last year, however, we have a deficiency of £8 14s. 7d. How this is to be made up must rest with you. It has been decided, in committee, that at our next meeting (April 3rd) we shall offer our surplus presentation prints for sale, thinking that perhaps many new members might like to possess them or have duplicate copies, while, perhaps, some of our debtors may be troubled with sleepless nights, and we may find some back subscriptions sent to us as conscience money, still further to reduce the above sum. At any rate, I hope something will be done to obviate my carrying the loss on to the present year, because I trust that in future we shall be able to keep our income up to our expenditure, and that when December comes I may find, if there be a balance at all, it will be on the right side, and I may be able to shake hands with myself and alter my tone, as "Old Dornton" does in *The Road to Ruin*, and say—"Oh! who would *not* be a *Treasurer!*"

INNOVATIONS IN PHOTOGRAPHY.

WE think it will be universally admitted that no photographer will wish to produce portraits by artificial light when it is possible to secure daylight. A crusade against artificial light is surely then scarcely more wise than Don Quixote's tilt against the wind-mill. Some of our correspondents have, however, been impelled to denounce portraiture by artificial light, and the present interest in it, as something utterly inimical to the interests and credit of the art and its professors. We can sympathise to a considerable extent with the real object of their opposition. This, we take it, is rather a possible, and, as they think, probable, result of the introduction of artificial light, than the use of the light itself. They fear that if artificial light for portraiture acquires anything like general adoption, the consequence will be an unwholesome kind of competition, degrading to the art; that night photography will be a common and inferior photography, of which there is enough already; and that respectable studios will be placed at an apparent disadvantage in the eyes of the public if they do not avail themselves of appliances to be found in commoner studios. They fear, moreover, that longer hours of work will become inevitable. Some will add that the great aim of enthusiastic photographers has for years past been to improve and elevate photography, and give its products the character of fine art, whilst the movement in question must have an inevitable tendency to lower the standard of work. There is something to be said for this view of the question. Unfortunately many of the opponents of artificial light portraiture are not discriminating in their attack, but utterly condemn the whole thing.

We must confess, on the contrary, we look with considerable favour on all experiments for applying artificial light to photographic purposes, and we regard every experimentalist in this direction as aiding materially in perfecting the appliances of the art. To object to the use of artificial light because sunlight costs nothing, is about as legitimate as to object to watering a garden or irrigating a field because rain costs nothing and answers the purpose better. No one, as we said at the outset, will willingly use a costly substitute when nature's more efficient agencies are available. But to what extent is daylight available in this country during a great part of the year? In the first month of the present year upon how many days was there any sunshine recorded at the Royal Observatory? During the thirty-one days of January last there were twenty-three days without any sunshine, and the total amount of sunshine during the remainder of the month did not amount to fifteen hours. During the fourteen days ending on the

fifth of February, the latest date to which we have record before us, there was no sunshine to record at all. But marshalling of figures is not necessary to convince photographers of a fact of which they have such bitter knowledge, namely, that during a great part of the year daylight is limited to very few hours, and during these hours it is often very bad. That there will also, at all times, be some to whom night photography is more convenient there cannot be a doubt, and the existence of a few establishments in a large town where night photography is practised need constitute no offensive competition with daylight studios who pursue their own course unconcerned as to their night competitors. A perfect mastery of the conditions of artificial illumination will, moreover, often prove of service during winter days when there is no efficient light and it is not convenient to close the studio.

"Decor Inemptus" takes exception to the expense of the experiment; but he conventionally overlooks the fact that Mr. Harman, whose paper at the South London Society seems to have elicited a burst of excitement, described an arrangement which might be very cheaply improvised. The portraitist whose choice or necessity may lead to adopt night photography as a part of his general practice will most probably purchase one of the most efficient forms of apparatus even at a high cost; but he whose aim is experiment, and the possibility of occasionally applying the light, will probably aim at cheapness, even if it involve improvising his own appliances.

"Decor Inemptus" gives some advice in which we can cordially concur, when he recommends portraitists to devote the hours of the slack season to remodelling arrangements, and, above all, to rearranging and cleaning specimens. We are occasionally shocked to see faded specimens hung in a dilapidated frame with a dirty glass in front. Specimens should not only be the best work the portraitist can produce, but in the best condition, and displayed to the best advantage. Where photography is followed as a business, the maintenance of respectability in connection with it is of quite as much importance as experiment to advance its technical qualities!

Amongst those who object to innovations in photography, as they regard all improvements which involve any radical change of practice, we have received communications from several who are anxious to stem the revolution which threatens to abolish the nitrate bath in the studio. Dry plates are to these correspondents an abomination to be denounced and exposed. The pressure on our space at the present time has compelled us to withhold many of these letters, which would have been interesting as illustrating the bitterness which can be excited in some cases by any effort to secure reform. Like Charles Mackay's "foolish preacher," our correspondents are disposed to cry out, "Change is rash, and ever was so: ye are happy as ye are!" On the other hand, it is to be remembered that invective is depressing to sensitive persons. We feel ourselves and our readers greatly indebted to those able and experienced correspondents who give in our pages the results of their experience for the instruction of others, and we scarcely care to permit them to receive in return the denunciations of those who fail to appreciate the value of the instruction.

BRITISH ASSOCIATION.

THE annual report of the Association is always full of interesting information, but it is, unfortunately, so late in issue, rarely having been ready until about the time of the next meeting, that much of its interest is lost. Owing, we understand, to the good offices of the President for the year, Mr. Spottiswoode, the report of the Dublin meeting has been issued earlier. The following extracts, relating to committees appointed, contain points of interest to photographers especially, as well as to all interested in the progress of science.

Committees Involving Grants of Money Appointed at the Recommendation of the General Committee.

That the Rev. Dr. Haughton and Mr. B. Williamson be a Committee for the Calculation of Tables of Sun-Heat Coefficients; that Mr. B. Williamson be the Secretary, and the sum of £30 be placed at their disposal for the purpose.

That the Committee, consisting of Mr. James Glaisher (Secretary), Mr. R. P. Greg, Mr. Charles Brooke, Dr. Flight, and Professor A. S. Herschel, on Luminous Meteors be re-appointed, and that the sum of £20 be placed at their disposal.

That Dr. Wallace, Professor Dittmarr, and Mr. T. Wills be a Committee for the purpose of reporting on the best means for the development of Light from Coal-gas of different qualities; that Mr. Wills be the Secretary, and that the sum of £10 be placed at their disposal for the purpose.

That Dr. Farr, Dr. Beddor, Mr. Brabrook, Sir George Campbell, Mr. F. P. Fellows, Major-General Lane Fox, Mr. Francis Galton, Mr. Park Harrison, Mr. James Heywood, Mr. P. Hallett, Professor Leoni Levi, Sir Rawson Rawson, Professor Rolleston, and Mr. Charles Roberts, be a Committee for the purpose of continuing the Collection of Observations on the Systematic Examination of Heights, Weights, &c., of Human Beings in the British Empire, and the Publication of Photographs of the Typical Races of the Empire; that Mr. E. W. Brabrook be the Secretary, and that the sum of £50 be placed at their disposal for the purpose.

Reports and Researches not Involving Grants of Money.

That the Committee, consisting of Dr. W. Huggins (Secretary), Mr. J. P. Lockyer, Professor J. Emerson Reynolds, Mr. G. J. Stoney, Mr. W. Spottiswoode, Dr. De La Rue, and Dr. W. M. Watts, for the purpose of preparing and printing Tables of Oscillation Frequencies of Solar Rays be re-appointed.

That a Committee consisting of Captain Abney (Secretary), Professor W. G. Adams, and Professor G. C. Foster, be appointed to carry out an investigation for the purpose of fixing a Standard of White Light.

BURNISHING.

BY J. KAY.

I AM led to write a little on this subject, owing to the number of advertisements that I have seen lately in the NEWS, by which photographers appear anxious to dispose of their burnishers; from which I conclude that, in their case at least, burnishing (that is, the process itself, not the results) is not a success. It is scarcely necessary to state that the results obtained by the successful manipulation of the burnisher are very desirable, and superior to anything that can be obtained by ordinary rolling. Not only are superficial defects of the albumenized print (such as scratches) entirely obliterated, but a highly glazed surface is imparted, which adds greatly to the beauty of the picture.

In giving a few directions for the guidance of those who are anxious to be successful with their burnishers, I shall state a few points of interest which occur to me as I mentally run through my experience in the matter; and the first point is the touching or spotting generally necessary upon the print.

If this be left till after burnishing, there are two objections mostly arising: first, the difficulty of spotting a surface that is more like a japanned tea-tray than a piece of paper; and second, the appearance of the spotting (dull, in contrast with the picture (bright), and this second intensified, should the defects be many and large. There is only one method known to me by which the spotting can be satisfactorily performed prior to burnishing, owing to the fact that the colour applied, when previously dissolved in water or gum-water, is dispersed when passed through the burnisher in the shape of a comet from the spot where originally deposited.

The method I allude to is to dissolve the pigments according to tone required, by the aid of a solution of albumen, composed of—

Pure albumen	1 part
Water	1 "

Shake well together in a bottle in which a few pieces of glass have been placed to cut and disperse the albumen, add two or three drops of pure ammonia, and the solution can be preserved for a long time. Mix up the palette entirely of the albumen solution and pigments, being careful to add no water, and when dry, no more albumen is required, the usual method being adopted, viz., the brush moistened in the mouth. This is important, for I have found in practice that albumen frequently used to dissolve the prepared pigment on the palette has created an excess, and in burnishing the spotting has cracked and left the surface.

The second point of interest is the lubricator, the preparation of which ought to be a very easy matter. Take one ounce of Castile soap, which may be obtained of any chemist for about one penny, and dissolve in sixty ounces of methylated spirit. The application of heat is essential to the thorough dissolving of the soap, or rather to the saturation of the spirit. Take therefore your bottle (a good strong Winchester quart will do) containing soap and spirit, and stand it on the hob, giving it a shake occasionally; and if at the end of five or six days there should be in the fluid, when cold, the appearance of thin fleecy clouds, add twenty ounces fresh spirit, and heat again, doing this until the supernatant liquid, when cold, is transparent, and of a faint yellow colour; decant, and apply to the picture with a soft rag, being careful to rub over the whole surface.

I find the ordinary Winchester to be capable of standing great heat on the hob. Let the stopper fit loosely, and raise it occasionally.

The third point of interest is, though apparently trifling, of great moment. I may be asked, how dry ought the print to be? This is a vital question. Should the print be very dry—bone dry, say—greater heat will be required to burnish properly; thus the tone of the picture will be affected considerably, and should the tone of the picture, before burnishing, be that required after, it will be impossible to secure it. The hotter the burnisher, the warmer the tone produced by it, and this I consider to be one of the manifest advantages of burnishing; for surely it must be an advantage to know, when one has a cold, mealy batch of prints, that some amount of warmth and beauty can be put into them, and render them fit to be seen. As a rule, the tone of the prints is, before burnishing, the same as that required after, in which case the cards must not be bone dry, but limpid; pliable, not damp; otherwise blisters are likely to appear; and, further, a highly glazed surface cannot be produced when the card is damp.

The last point that I shall introduce is the scratching of the burnishing plate. This is caused by grit, small particles of which are often found in the cards, and are injurious in this respect in those portions of the cards exposed, viz., at the top and bottom and sides. This is the most prolific source of scratches, though sometimes grit is present in the mounting material. I find the best way to detect this source of annoyance is to pass the print through the burnisher once, and then examine it; should there be any grit in that end of the card first inserted, the scratch will appear on the surface, and should there be any in any other part of the card it will have done its work on the metal, and the second time, should the card be passed through in the same place, every defect will appear. It is always advisable to examine the card each time after passing through twice; after that, if all be right, there is, as a rule, nothing to fear. Always put the card through the same way; don't reverse it, and, as nearly as possible, in the same place. These two hints, if attended to, will save many troubles. Should a scratch appear on the surface of the card, it can generally be traced to its fountain head—a little grit in the card. Remove with the point of a penknife, and after polishing the burnisher pass through again. Should the scratch be very deep, and the grit very

large, my advice is have nothing more to do with the picture; a deep scratch can never be properly removed, if you burnish again a dozen times. To remove scratches from and to polish the burnisher, procure a block of hard wood, about four and a-half inches long, two and a-half inches wide, and one and a-half inches deep. Cut the polishing paper into strips of any suitable size (five inches by three inches will do), and then fold round the wooden block, rubbing the burnisher lengthways, which is the contrary direction to that in which the pictures are passed through. The finest polishing paper is essential, and as photographers, particularly those in the country, may have a difficulty in getting it (I have been able only to get it at one place in London), for their assistance I add a few particulars concerning it. It is commercially known as "OOO Polishing Paper," and may be had at 2d. per sheet, or 4s. per quire, of Mr. J. Buck, 56, Holborn Viaduct, E.C.

Notes and Queries.

MOIST COLLODION EMULSION.

DEAR SIR.—In an article in the YEAR-BOOK of 1879, on "Emulsion Collodion versus Gelatine," Mr. William Brooks refers to a glycerine preservative for moist emulsion, which, to my mind, appears so simple and effective, that if he would kindly publish details of his formulæ for plates and development of same, I feel certain it would be of interest to your readers, and would confer a favour on your humble servant,

THE CLYDESDALE LADDIE.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

The monthly meeting was held on Tuesday evening last at the Water-Colour Gallery, Pall Mall; the President, Mr. JAMES GLAISHER, F.S.A., in the chair.

The minutes of the preceding meeting having been read and passed,

The CHAIRMAN read the Report of the Committee recently appointed to consider the management of the Society's Journal. The report had been laid before the Council, and approved. The purport of the recommendation was, that in future the proceedings should be reported as nearly *verbatim* as possible, and that the Journal should be published on the next Friday but one following the monthly meeting. [This will delay the appearance of papers in these columns.]

The discussion on Mr. C. Bennett's paper on "Gelatine Emulsion" was then resumed.

In the absence of Captain Abney, who was unable to attend in consequence of family bereavement,

The SECRETARY read a paper on "The Effect of Prolonged Emulsification in Gelatine Bromide," in which Captain Abney described certain experiments, and the theory he had deduced therefrom.

Mr. BEDFORD then read a paper on some experiments with various coloured glasses for photographic purposes. He passed round the results of his trials of different examples of glass by direct light; in each case the sample of coloured glass was placed in juxtaposition with the photographic result. As a rule, he found that though a single thickness of ruby glass was superior to one of orange, two thicknesses of the latter were preferable to one of ruby; and that with sensitive bromide plates, three thicknesses of orange glass would give a perfectly safe light, and comfortable to work by.

Mr. BEDFORD also exhibited a print from a negative on a Bennett plate, which had been exposed four months after preparation, and developed seven months after exposure, with most satisfactory results.

Colonel WORTLEY read a paper "On the Action of Nitrate of Silver in the Production of Red Fog," in which he stated that personally he had complete immunity from this defect, a fact which he attributed to his employment of nitrate of uranium in the emulsion. He exhibited two bottles containing gelatine, to one of which nitrate of silver alone had been added, to the other

nitrate of silver and nitrate of uranium. The former presented a reddish brown appearance, while the latter was colourless. In explanation of the action of silver on gelatine, the Colonel showed two bottles containing respectively gelatine and collodion, which had been exposed to the light in contact with nitrate of silver; the former had acquired a deep brown colour, the latter remained unchanged. He went on to say that he considered that the quality of gelatine greatly depended upon their being treated throughout in such a manner that the various operations were in harmony. As an instance, he said that Mr. Bennett emulsified for some days at a low temperature, while he (Col. Wortley) emulsified for a few hours at a high temperature; and yet, when exposed together a short time previously, their plates were found to be equally sensitive. He concluded by quoting from the *British Journal* of November 14th, 1873, the first published account of washed emulsion.

Mr. SAMUEL FRY next read a paper on his experience with gelatine plates in the studio, and showed two fine negatives taken that day with exposures of less than one second. In the course of his remarks, Mr. Fry said he did not think he should ever use the bath again. With regard to the uncomfortably dim light recommended for these plates, he might say his laboratory, which was of considerable size, contained two windows about six feet by four each. These were covered with four thicknesses of yellow paper, which gave illumination sufficiently non-actinic and comfortable for work.

Mr. HERBERT B. BERKELEY read some notes on gelatine emulsion, and showed a number of specimens in illustration. Amongst other matters, Mr. Berkeley alluded to the vagaries of alcoholic gelatine emulsion, and to the possibility of working with an excess of silver.

Mr. WAINWRIGHT, Jun., said that gelatine had been said to be not under control as regarded exposure and development. In refutation of this charge he passed round a plate, one-half of which had been exposed for three-quarters of a minute, the other half for five seconds, and the development carried out to suit the longer exposure. He thought this showed that gelatine plates were under control.

Mr. CHARLES BENNETT, in response to the Chairman, undertook to reply, in the form of a paper, at the next meeting, to the various communications which had been made that evening.

Mr. W. COBB asked if any gelatine workers had noticed a discolouration of their negatives under the action of light. His negatives, many of which were intensified with iron and silver, gradually acquired a red discolouration during printing, and some had become wholly useless from this cause.

Col. WORTLEY thought it was due to the action of the intensifier. Gelatine plates required far more washing than collodion, and if the slightest trace of hypo were left in the film it would inevitably ruin the plate.

Mr. WHITFIELD was understood to say that he had employed the iron intensifier without experiencing the result complained of by Mr. Cobb.

Mr. BENNETT said that in addition to washing well after fixing, the plates should be dried at once, in order to prevent frilling.

Mr. COBB said that in one or two cases, finding his negatives too dense, he had been able to reduce them by means of a solution of hydrochloric acid in water (a solution of one part in eight).

Mr. T. SEBASTIAN DAVIS showed a couple of transparencies of a group of members of the Society in the act of shaking hands on their departure from a friend's home. The figures were all in motion, and Mr. Davis explained that the negatives were taken by Mr. Bennett with a drop-shutter after half-past-five, one evening last week, only half-an-hour before sunset.

The proceedings then terminated.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Thursday evening, the 27th ult., at the Free Library, William Brown Street, Mr. THOMAS CLARKE, President, in the chair.

The minutes of the previous meeting were read and confirmed.

The President, Treasurer, and Secretary were appointed delegates to attend the meetings of the Associated Societies of the literary, scientific, and art societies of Liverpool.

Mr. H. HOULGRAVE exhibited a number of negatives, with their corresponding prints, which had been taken in illustration of his paper read at the February meeting. He (Mr. Houlgrave) said that with gelatine plates generally the difficulty was to avoid getting the negatives either too hard or flat. By his method he secured negatives giving beautifully soft prints.

He developed with carbonate of ammonia, and, as far as he had been able to try them, he thought there would be no difficulty in working them in such a climate as the West Indies, for which purpose he was carrying on his experiments.

The PRESIDENT, in moving a hearty vote of thanks (which was passed) to Mr. Houlgrave, alluded to the beautiful delicacy of the negatives exhibited, and expressed a wish that Mr. Houlgrave should submit some of his views to be selected for a presentation print.

Mr. HOULGRAVE replied that, unfortunately, he did not think he had any of sufficient pictorial interest, or he would have gladly done so.

The Council reported that Mr. Tyrer's negative of the "Old Hut," and Mr. J. H. T. Ellerbeck's of the "Castle of Chillon," had been selected for presentation prints, and their selection being approved of, the Secretary was requested to make arrangements for the printing.

A lantern exhibition closed the proceedings, at which Mr. Meacock exhibited a lantern with three wicks against one with two, and Messrs. Clarke and Bucknall contributed a number of fine transparencies.

The meeting was then adjourned until the 21th instant.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY
The Association met on the 17th January last, under the presidency of Dr. VOGEL.

The CHAIRMAN laid before the meeting some collotype prints in colours by Herr J. B. Obernetter, of Munich. His method is to reproduce from the same negative, by the powder process, a number of other negatives under various degrees of exposure, so that the different parts are more or less covered, according to the time of exposure. From these negatives collotype plates are produced, and the latter are then rolled up with the properly selected colours.

Herr OBERNETTER also sent a communication on dry plates, in which he pointed out that gelatino-bromide surpasses any other kind of film in sensitiveness, but requires troublesome manipulation in drying and developing; he therefore prefers collodion emulsions for general work. This emulsion he now prepares himself, using as little pyroxyline as possible, and the plates, when they have been coated, and the film set, he places in a solution of—

Nelson's gelatine	2 parts
Alcohol	60 "
Lukewarm water	40 "

and afterwards puts them to dry in a vertical position. By this means great sensitiveness is obtained, the plates also retaining the impression of light, while plates that have not been covered in this way go back after a short time, so that it is necessary to develop them immediately after exposure.

Herr MARTINI exhibited some negatives on gelatine plates of Messrs. Wegner and Motter, of Amsterdam, after an exposure a little shorter than that required for wet plates.

Herr PRUMM advised dealers and manufacturers to be very careful in packing plates for transmission; he complained of having received several packets of dry plates in which a number were spoiled by the light penetrating, owing to defective packing.

Professor VOGEL exhibited two portraits taken with an exposure of two seconds in December by W. Cobb, of Woolwich, on gelatine plates of Messrs. Wratten and Wainwright, which, in regard to delicacy, left nothing to be desired. Particularly worthy of notice is the detail in the white linen, which in ordinary negatives always appears over-exposed. The speaker attributed the latter defect to irradiation produced by reflection from the after surface of the plate, and remarked that in his own photographs of the spectrum taken on gelatine plates he had never observed this phenomenon, even when they were considerably over-exposed; whereas with collodion plates it almost always made its appearance. He held this to be a great advantage in using gelatine plates, especially as it was completely in the power of the maker to increase their sensitiveness to any extent, by keeping the emulsion in a fluid condition for a longer or shorter time before he allowed it to set. Wratten and Wainwright, with whose plates he had lately been experimenting, keep two kinds in stock: ordinary ones, which are said to be equal in sensitiveness to wet plates; and instantaneous ones, which are from ten to twenty times as sensitive as the latter. As regards the first of these, he had found that, employing the developer recommended by Wratten, the sensitiveness was about half that of a wet plate; but by increas-

ing the amount of ammonia in the developer to six times that advised by Mr. Wratten, he had been able to bring out an image to a sufficient extent after a shorter exposure than that required for a wet plate.

Herr SCHAARWACHTER was of opinion that the phenomenon of irradiation could generally be avoided by an adequate acidulation of the bath; he also expressed a doubt whether gelatine plates were always free from irradiation.

Herr SELIGMANN stated that he had met with irradiation on gelatine plates; but the Chairman believed that this effect could only be possible when the bromide film was too thin and semi-transparent; the films with which he had experimented were perfectly opaque.

Herr PRUMM insisted that the gelatine processes were deserving of very close attention on the part of photographers. The films were sometimes astonishingly sensitive, but the development was attended with much that is disagreeable and tiresome. It took a long time, and could not be so well watched as in the case of ordinary plates. The intensification was also difficult. Altogether he believed that further experiments on the subject were highly necessary.

At the meeting of the 7th February, Professor VOGEL, who again occupied the chair, read two letters on the subject of the fading of carbon prints. In the first of these Herr A. ORT maintains that the permanence of colour in the gelatine film is thoroughly assured provided a reliable pigment be employed. For this purpose he advocates the use of alizarin, which, as he asserts, cannot be less durable in conjunction with gelatine than it is when taken up by animal or vegetable fibre. The theory of Dr. Monckhoven, that an insoluble chromate is retained by the paper, is combated by Herr Ort, on the ground that when uncoloured films of chromate gelatine are washed in hot water, the yellow colour due to the chromate of chromium is changed to green, caused by the perfectly inert chromium oxide. Any one, Herr Ort adds, can convince himself of the permanence of alizarin, by exposing gelatine coloured with that substance for seven months to strong sunlight, at the end of which time it will be found to be unchanged; but all preparations of cochineal must be put on one side as quite useless. The second letter came from Herr Tönnies, of Aalborg, in Jutland, and was to the same effect as that of Herr Ort. According to the former, it rests entirely with the manufacturer and his choice of a permanent colour, whether his carbon prints can stand a long exposure in a show frame.

Herr REICHARD remarked that some transparent carbon pictures which he had taken two years ago, and which since then had been exposed fully to the light, and to all the changes in the hygroscopic condition of the atmosphere, as well as to variations in temperature, had to a certain extent lost their warm brown tone, but in every other respect were unaltered. They were liable to peel off when the substratum was one of collodion, but not so much as when chromated gelatine was used for that purpose.

Herr STEFFENS had never noticed the peeling off even with a collodion substratum, but Herr Kuntze had suffered from it in the case of larger pictures, and had been able to prevent it by varnishing them.

Herr SCHAARWACHTER had observed that carbon pictures fixed in the window-panes of properly heated rooms soon peeled off, while those in the windows of corridors that are not artificially warmed remained perfect, and that without studying their being subject to washing with water every three months. The Chairman observed that the washing was a very hard test, but that windows in corridors were not so much exposed to variations in the hygroscopic conditions of the atmosphere and in temperature as the windows of a room.

Herr FAHLING remarked that carbon positives were apt to peel off in the places where they had been retouched.

Herr RICHTER had experimented with a glass carbon picture by covering the half of it with cardboard, and then exposing it in a copying-frame during extreme summer heat; he found, on removing it, that the uncovered part had peeled off, while the other half remained in good condition. Pictures that had been worked in oil colour showed no signs of peeling.

Herr QUIDDE opened a discussion on a defect in albumen, which, though not previously unobserved, he had only himself met with during the last few weeks. The film of albumen was loosened by the baths to such an extent that when the plates were removed from the fixing bath it could be rubbed off by the least touch with the finger, and in some cases came off of its own accord.

Herr REICHARD ascribed this phenomenon entirely to the intense cold that had lately prevailed. The silver bath, he maintained, ought never to be lower in temperature than 15° R.; with a temperature in the silver bath and drying room of 2° to 4° R., the defect observed by Herr Quidde was very apt to occur. Of course the paper employed was a factor in the case, as some kinds of paper were able to stand greater cold than others. In reply, Herr Quidde was inclined to agree with the last speaker, as in the case he had alluded to, his silver bath had often been near freezing, and so soon as the weather got warmer the defect disappeared.

Herr SCHAARWACHTER believed that with some kinds of paper the same difficulty would be met with at a comparatively higher temperature; in such cases he had avoided it by silvering the paper for three or four minutes, instead of the usual two minutes.

Herr ROLOFF had heard from good authority that in order to increase its glossiness, albumen paper was sometimes adulterated with gelatine; but the Chairman doubted this, as gelatine is dearer than albumen.

Herr BOLL showed a camera with an arrangement for electrifying the plate. The slide is made to move on brass guides (both above and below), each guide being connected to one of the poles of a weak galvanic battery. At two opposite corners of the slide are fixed a couple of wires arranged to touch the plate so that the electrical current shall flow diagonally across it, and pressing the other extremity by springs on the brass guides. In front of the objective is a pneumatic shutter, which is connected by an ingenious mechanism with the above arrangement, so that when the shutter is open contact is made, and when closed it is broken. By this means the electric current passes across the plate only while the light is acting on the latter.

REPORT OF THE PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

The following is a digest of the proceedings of the meeting held on December 3rd, 1878, President NEWTON in the chair.

The minutes of the last meeting having been read and confirmed,

Dr. HIGGINS said that he would like to make a few remarks in relation to the matter of exposure, or rather over-exposure. When a sensitive plate was exposed to the actinic influence for a certain length of time, which gave what was wanted as far as the production of the image was concerned, it was called a normal exposure. If that exposure were made considerably longer, it was termed an over-exposure. What was the usually recognized effect of a much prolonged over-exposure upon a sensitive plate upon the high lights?

PRESIDENT. It would depend to a very great extent what the effect is upon the high lights; what the sensitive salt was, or its combination. A bath plate over-exposed produces what is called solarizing on the high lights. An emulsion plate, or certain kinds of emulsion, did not present that phenomena; the plate could be exposed with impunity almost without the high lights solarizing in development. Where an object presented violent contrasts in the strong sunlight, like black and white, or white exposed to the glare of the sun, and the shadows were black, to make a picture by the bath process that would represent that truly would be next to impossible, because before the detail in the dark shadows and blacks could be brought out, the high lights would be overdone. With a dry plate or a wet emulsion plate properly prepared, there was great latitude.

Dr. HIGGINS; Then I understand that there is greater latitude of exposure recognized in the emulsion plate than in the bath plate?

The PRESIDENT; I so recognize it; but I don't speak for anybody but myself.

Mr. CHAPMAN said that his experience as to the bath plate compelled him to differ with the President; that no matter how strong a contrast there might be, that by a prolonged exposure, though the high lights commenced their action sooner than the other, they did not continue with that rapidity, from the fact that the iodide of silver was almost perfectly non-actinic by transmitted light, and that the shadows caught up, so to speak.

Mr. ROCHE stated that his experiences in California and Washington, where the high lights were very strong and the shadows very deep, induced him to alter his collodion, reducing the iodide and increasing the bromide, when he got a very fine set of negatives, the relative proportions being five of iodide and three of bromide.

Mr. CHAPMAN said his collodion had the same proportions, and he had always found that to be a very fine working collodion, and

that his results might be due partially to the salt in the collodion as well as the prolonged exposure.

Dr. HIGGINS asked what was meant by latitude of exposure? His inquiry was in reference to the matter of high light, simple high light and absolute shadow. By the term latitude of exposure we would infer that you can expose too long for the high light. Are we taught that after a certain time, and not a very great length of time, a reverse action of the sun takes place, and the image goes back?

The PRESIDENT stated that his manner of exposure, if the sun were at his back, and the shadows consequently few and not strong, was to give a very short exposure. If the sun struck the picture at right angles, and the shadows were very heavy, he judged by what he could see of the detail on the ground glass, without reference to the high lights at all, how long it would take to get the detail out of the darkest shadows, and exposed accordingly. In different localities, and on different days, the light was entirely different, that a person had to become familiar with the appearance of the light; and to expose a dry plate with any certainty, he required considerable experience, and must then be sure to expose enough, because he had great latitude. In case of over-exposure, the developer could be modified so as to produce equally good negatives from a plate exposed two minutes and a plate exposed one minute.

Dr. HIGGINS; Take a white image with a black cloth behind it; there you have simple high light and absolute shadow. Now, I want to know what becomes of an over-exposure there on that high light? Have we such a thing there as an over-exposure? We give a certain exposure, which we say is a normal exposure. Now if you increase, double, triple, quadruple, what will result; will it be more intense, or are we taught that it will weaken?

Mr. ROCHE; With the bath plate we know we have fog, but with emulsion the result is altogether different.

The PRESIDENT; If you take a positive and put it over a dry or wet emulsion plate in the sun, and let it lie five minutes, you will have from that negative a duplicate negative. Everything is reversed, that is, with the bromide emulsion.

Mr. BIERSTADT stated that the process described by the President, which was also his experience, would seem to prove that a prolonged action did reverse; but that he should differ with the President in saying that emulsion had great latitude, and say that it had very little.

Dr. HIGGINS exhibited to the Section a picture taken upon a dry plate, one-half of the plate having been given a normal exposure of one second, and the other half an over-exposure of one hundred seconds. The way in which the experiment was made was as follows: A negative prepared for the occasion of black and white circles, resembling the ordinary sharpshooter's target, was placed in the printing-frame, the dry plate was superimposed upon it, and exposed as a whole for a second to the light. It was then taken in the dark room, and there was interposed between the two—i.e., the negative and the sensitive plate—a piece of cardboard covering one half of the plate. The whole was then exposed to the light for one hundred seconds. The half which was covered had one second exposure, and the half which was uncovered had one hundred. In examining the plate you will see a beautiful penumbra or shadow caused by the interposition of the mask between the negative and the sensitive plate. This experiment showed that the image had not gone back. The emulsion was a bromo-iodo chloride emulsion! It was the generally received opinion that by a greatly prolonged over-exposure the high lights would go back again. In *Hardwick's Chemistry* reference was made to such fact in the experience of Mr. Mason, where he called attention to the alternating action of light upon a sensitive plate. This experiment showed conclusively that upon a bromo-iodo-chloride emulsion plate, at least, that such is not the case; that exposure might be indefinite, and that the action of the high lights would be simply more and more marked.

Mr. MASON; Perhaps Dr. Higgins' experiment is not in exact accordance with the experience of landscape photographers from this fact—the Doctor has there the high light and the shadow, as he terms it, the two extremes contrasted. Now, why does a plate under the developer present this appearance, which is termed "going back," or the negative being thinner, made by a long exposure? Let us ask ourselves what forms the image; what is the action of the developer? The developer acts most readily where the light has been the strongest; there we get the longest deposit of silver. If we put on a sufficient amount of the developer to flow that silver off, of course it has left the entire surface of the plate; but if we keep that silver on—sup-

pose we have a spot of white in our picture—there we have a great deal of silver deposited at once, while on the shadow there has been very little deposit. Now, if you continue the action of the developer, and there is yet free silver left on the plate, it commences to deposit on the shadow portion, when the light has been weak, and the contrast is immediately reduced by this deposition of silver on the shadow portions, and the contrast decreases the longer we continue that action up to a certain point.

Dr. HIGGINS called attention to the fact that the plate exhibited was a dry emulsion plate developed by the alkaline developer, in which there was no silver used.

Mr. MASON said that the silver in the film was effected in quite a similar way.

Mr. NEWTON: It is a fact which has been proved that by long exposure the action is reversed. All that is lacking here in the Doctor's experiment is time.

Mr. BIERSTADT: In this experiment of making a negative direct from a negative, I took an emulsion plate and put it in contact with a negative in an ordinary pressure-frame and laid it in the sunlight. If that was given one hundred seconds in a camera, what would the exposure have been to correspond with the six minutes I gave it in the sun? In the light I had, the one-hundredth part of a second would have been overtime, and I gave it six minutes.

Mr. NEWTON: You will see the difference between that experiment and the Doctor's. That dry plate would undoubtedly have been over-exposed for the production of a positive in one-twentieth of a second in broad sunlight. Consequently he gave it six thousand times more than the time required to make a positive, allowing five minutes' exposure. If the Doctor, instead of giving one hundred times more, had given about six thousand, he would have obtained probably the same result.

Dr. HIGGINS: The deduction from what I have said is simply that practically we need not fear an over-exposure in reference to our image disappearing. Theoretically and absolutely also, as a matter of fact, we recognize that the image will disappear, but if a one hundred times' over-exposure does not cause it to do so, and it needs six thousand or more times, I think that practically we need not fear it.

Mr. BIERSTADT exhibited a few specimens of the new process of printing called the "Artotype," stating, in answer to inquiries, that the difference between the Artotype and the Albertype consists in the use of specially prepared materials, such as gelatine, ink, paper, &c., applied to plates so as to insure a fine grain and to give increased brilliancy. By the Albertype process it would require two and a half hours to dry a plate, and by this process only twenty minutes, washing it in twenty more, and it is ready for the press. The paper used should have a very fine surface. Ordinarily a good printed would print, perhaps, three hundred impressions in a day. As to the cost compared with silver prints, it would cost a man's time; the cost of the material was nominal. Paper enamelled and varnished is less than half the cost of albumen paper, and silver was not used. Lampblack is quite cheap, and one pound of printing ink will make several tons of pictures. I have not tested its capacity for printing; the most I have taken is eight hundred from one plate, and still the plate was as good as any plate I have ever used by the old process, and I have printed forty-five hundred impressions from one plate by the Albertype. We can continue to print day after day from an Artotype plate, or we can use a plate and let it lie for a week, and then begin again with it.

Mr. ROCHE exhibited a few pictures made by a similar method, and explained his process, which he called the typograph.

Dr. HIGGINS ask if it is the generally received opinion in emulsion plate photography that a preservative is what its name imports; if it is necessary for a dry plate when put away for future use?

The PRESIDENT: One of the essential elements is the presence of free silver on the bath plate. Every one who has tried to develop a bath plate after thoroughly washing it has made a failure. Now whether a bath plate or an emulsion plate, after being thoroughly washed in order to develop an image on it, it is necessary that something should act as a substitute for the silver. Organic matter has been recognized generally as acting to a certain extent as the required substitute, giving force and character to the negative. Originally it was called a preservative, because it was supposed the keeping qualities of the plates were improved. Any photographer knows that nitrate of silver is not sensitive to light except in the presence of organic matter. Here, however, organic matter acts an important part in presence of bromo-iodide of silver

instead of free nitrate of silver. About a year since, in an editorial in the *British Journal of Photography* on the subject, was maintained that the organifier did not act in any sense as an accelerator, or in any way increase the sensitiveness of the plate. This view is not in harmony with my experience. I find that marked differences result from the use of different substances to organify the plates. In the article referred to it was maintained that the organic matter gave additional vigour and intensity, and that only; and this fact had led the mind to erroneous conclusions. I find that with some organic substances the sensitiveness of the film is very much greater than without any, and I find that my conclusions on this subject harmonize with those of a large class of experimenters.

Mr. CHAPMAN: I think that, aside from the organifier, that it is fully recognized, and borne out also by experiment, that certain things applied to a plate preserves the latent image from deterioration after exposure.

Dr. HIGGINS: Mr. Chapman's view of the meaning of the term preservative is different, I think, from that usually accepted. The term preservative, as he used it, refers to the keeping of the latent image. Such being the view usually held, on the second of last March, I showed a number of emulsion plate, put them by in a box, using no preservative on them. On December 2nd, exactly nine months after, I exposed them. The exposure was in every way similar to what it would have been upon a wet plate; not the same as if it had been a preserved dry plate, I mean, because my preserved dry plates are much more rapid than my wet ones. On the usual exposure, then, of a wet plate being given to them, the images appeared. There was no organifier in the emulsion.

Mr. CHAPMAN thought that the bromide emulsion plates do not require any preservative, so far as the keeping qualities of the plate are concerned; that all that is required on emulsion plates is to preserve the latent image after it has been impressed upon a plate.

The PRESIDENT: An ordinary emulsion dry plate, used in its normal condition after washing, I consider about as sensitive again when dried with a preservative on. If the wet plate is used with the accelerator, that makes it much quicker than the dry plate; in my experience, about four times as quick. Some time ago Capt. Abney published an article bearing upon this subject. He made a series of experiments, and claimed to have demonstrated that tannin would not preserve an emulsion plate so that the image could be developed after a certain time had elapsed after exposure, but that by the addition of gallic acid the emulsion plate would retain an image indefinitely after exposure. Whether his conclusions have been verified by any other experiments or not, I do not know. I have never seen any statement bearing upon the subject at all. He is very reliable as an experimenter.

The Section then adjourned.

Talk in the Studio.

PHOTOGRAPHY OF ANIMALS IN MOTION.—The *Times*, referring to Mr. Muybridge's experiments, says:—"One might expect that the art of instantaneous photography would throw a good deal of light on certain problems of animal locomotion. It is known that Mr. Muybridge, of San Francisco, lately obtained a series of photographs of horses in various modes of progression (even in full gallop) and at various stages of the movements, with highly encouraging success. These experiments were made at the instance of Governor Stanford, to whom the idea occurred from reading Professor Marey's remarkable work on animal mechanism. We hear that Mr. Muybridge is about to develop and extend his experiments. With this view he has had constructed thirty cameras with electric screens. For photography of horses, these will be placed about one foot apart from each other. The experiments are to be commenced in May, and Mr. Muybridge proposes to fix all attitudes imaginable of athletes, of horses, of cattle, of dogs, and other animals in motion. Professor Marey lately suggested that the method should be applied in studying the flight of birds, and Mr. Muybridge intends modifying his apparatus for this purpose. Of course, this case presents special difficulties. We may state that a French captain, M. Vassel, has proposed in *La Nature* an apparently feasible way of realizing M. Marey's idea of a 'photographic gun' (so called) for fixing birds in their flight. The gun, which is fitted with Bertsch's automatic camera-

obscure, is actuated by means of a trigger, but this trigger, instead of the usual action, releases a rectangular sliding screen, which has a round aperture in the centre to let the light pass, while it intercepts it by its two extremities. Should it be desired to produce at one operation a series of successive attitudes, the construction of a 'photographic revolver' would offer no greater difficulty than the gun described."

THE PLACE OF MINIATURE IN ART.—At a meeting of the Society for the Encouragement of the Fine Arts, held on the 20th ult. at the Galleries, Conduit Street, Captain Mercier in the chair, a lecture was delivered by Mr. J. W. Bradley, on "The Place of Miniature in Art." The Chairman remarked, in opening the meeting, that Mr. Bradley (the lecturer) was an authority on the subject which he designed to treat that evening, he having travelled from Edinburgh to Naples—in fact, all through Europe—culling information on the subject in every part. The lecturer then proceeded to show that miniature was the mirror of art in all ages, and, of course, particularly so in the middle ages, when miniature painting was so much in vogue. He pointed out that where other monuments were wanting, miniature painting was itself the link which bound preceding and the succeeding styles of art. He enforced this by various examples, which he gave, and comparisons of manuscripts of different ages, with the existing monuments of those ages; the argument being that in some cases where there were no monuments, the manuscripts containing these miniatures might be trusted. By miniature painting he meant the illustrations which it was once so much the vogue to illuminate written books with. The art went back to the days of Cæsar, and began with the days of Varro, who died 23 B.C., and from that time for nineteen centuries the practice had been continued. Varro's portraits were multiplied by some mechanical process, afterwards lost. The ordinary idea of miniature was painting in little, but this was not the strict meaning of miniature, which really meant painting in minimum. A miniature could be grand just as a wall or a ceiling might be mean. Littleness was in point of stature, not in intelligence, and a miniature of the middle ages should be measured not by its dimensions, but by the ideas which it conveyed. A Bible was extant in Paris which contained several thousands of these glorious paintings, which was valued at £4,480, according to the price which each miniature would cost at the present day.—*Daily Chronicle*.

USED IN HIS BUSINESS.—*Funny Folks* says:—"Oh, those jurymen! An inquest was lately held on a poor photographer. A doctor explained that death had resulted from an effusion of serous fluid on the brain. A juror asked whether the fluid was one that the deceased used in his business, and, if so, whether it could have got into his system, and there proved fatal!"

CEMENT FOR GLASS.—Take 10½ lb. of pulverized stone and glass and mix with it 4½ lb. of sulphur. Subject the mixture to such a moderate degree of heat that the sulphur melts. Stir until the whole becomes homogeneous, and then run it into moulds. When required for use it is to be heated to 248°, at which temperature it melts, and may be employed in the usual manner. It resists the action of acids, never changes in the air, and is not affected in boiling water. At 235° it is said to be as hard as stone.—*Scientific American*.

To Correspondents.

TO AGENTS AND ADVERTISERS.—Next Friday being Good Friday, the PHOTOGRAPHIC NEWS will be published on Thursday, April 10th. Advertisers should send in their Announcements not later than Wednesday, the 9th.

F. H. D.—Mr. C. E. Elliott, of 36, Jewin Street, E.C., is the London Agent for Darlot. We do not remember his Paris address, but Mr. Elliott could doubtless supply it; or "Darlot, Optician, Paris," would probably find him.

ACETIC.—The gold toning bath becoming purple indicates that the gold is precipitated. This may arise from several causes, such as contact with a reducing agent, the action of light and heat. Warming the bath will decidedly contribute to such a result. Making the bath too strong will so contribute, and using seven grains of chloride of gold to forty ounces of water will give a solution somewhat strong for the purpose. A good bath for immediate use may be improvised by pouring boiling water on chloride of gold; but we should not think it would be a good keeping bath.

XX.—The stain on the print you enclose is caused by hypo. Probably caused by the use of a dish which had contained hypo for rinsing the unfixed print.

B. R. S.—So far as we know, artificial light has not been used to any great extent as an aid to daylight on dull days; but it has been used to some extent. Magnesium wire or ribbon has been found most useful in such cases. A small portion burnt—just sufficient to give brilliant points of light on the illuminated side of the face—is very valuable, and greatly improves the quality of a negative. In what is termed "Rembrandt" lighting it is especially useful.

R. M. D.—We prefer about ten ounces of water to one grain of chloride of gold. There is no advantage in a stronger solution. The acetate formula is as good as any. It was originally proposed by Mr. Hannaford.

R. G.—With a good English paper, no previous preparation was required before applying the collodio-chloride of silver; but with ordinary samples of photographic paper we found a sizing of arrow-root beneficial. A somewhat old and weak toning bath answered well. The bath of sulpho-cyanide of gold always pleases us best for toning collodio-chloride pictures. We first published the process in the winter of 1864, and read a paper before the Photographic Society in the spring of 18 5.

F. F.—We cannot advise you as to the relative value of portrait photography and landscape photography as a matter of business. There is, of course, much greater demand for portraiture than landscape, and there is also a greater supply to meet the demand. Individual experience and observation are the most satisfactory guides.

B. J. M.—Want of vigour in the negative may result from many causes. A bad light, a slow lens, newly-mixed collodion, insufficient pyroxyline in the collodion, pouring on the developer so as to drive the free nitrate off the plate, and a variety of other causes will cause this defect. It is difficult to indicate the cause in operation in individual cases without a full knowledge of the circumstances. 2. A thin negative is best printed in a dull light. Printing in full sunlight will give a soft, flat image with many thin negatives which, printed in the shade, will give vigorous prints.

J. KAY.—Many thanks. The subject is interesting.

FREDERIC B.—We did not see your first communication until it was in print, being ill at the time. Our intimation was, however, intended for you, and if you call until you secure the intended audience, we think it may serve you. The *nom de plume* was that of an old correspondent, and we felt in danger of losing his identity; but there is no harm done.

G. A. S.—The pyroxyline which we have found best for preparing collodio-chloride of silver is made by using equal portions (by measure) of nitric acid sp. gr. 1.420, and sulphuric acid sp. gr. 1.840; in six measured ounces of the mixed acid place two drachms of fine clean cotton wool. The mixed acids should be brought to a temperature of 150 Fah., and the cotton kept there ten minutes, kept moving all the time by means of a spatula, to ensure perfect action throughout all the cotton. This gives a collodion not too tough, nor too powdery. Use equal portions of sulphuric ether and alcohol at 82°.

HAAKMAN.—Many thanks. A detailed answer in our next.

W. H. M.—We have no doubt whatever that the yellow stains are due to hyposulphite of silver, but how brought there is the difficulty. Some of them have much the appearance of resulting from air-bells formed on the print whilst fixing, and so preventing the fixing solution from perfect action at the point where the bubble is formed. If you realize what takes place when a print is placed in the hypo bath, you will better understand the case. The first thing that happens on contact between the print and the fixing solution is a formation of hyposulphite of silver. This substance is not soluble in water, and is very unstable, quickly decomposing, and causing a yellow stain. It is soluble in a strong solution of hyposulphite of soda, and is, as a rule, dissolved in the fixing bath as soon as it is formed, the formation of a double hyposulphite of soda and silver being the result. This is soluble in water, and is removed by washing. The simple insoluble hyposulphite of silver once formed, and not redissolved at once by excess of hyposulphite of soda, cannot be dissolved or removed afterwards, and causes these yellow stains.

W. HALL.—We did not intend to put any unfair construction upon your letter; but in the interest of the art we felt it right to withhold from publication depreciatory remarks upon many able and liberal men who were doing their best to advance the art and to instruct their fellows without possible reward of any kind. We do not misappreciate your motive, but think you had not duly considered the question in all its bearings.

E. C. MURRAY.—The subject is an interesting and important one. In our next.

A SUBSCRIBER FROM THE FIRST NUMBER in our next.

J. L.—In our next.

Several correspondents in our next.

The Photographic News, April 10, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE IMPORTANCE OF PHOTOGRAPHIC RECORDS—OBERNETTER'S CHROMO-COLLOTYPE PROCESS—THE INFLUENCE OF AMATEURS.

The Importance of Photographic Records.—An excellent example of the use of photographic records was afforded the other day at a meeting of the Society of Naval Architects. The subject of building armoured men-of-war is once again being widely discussed, and the question is whether we are to have any more battle-ships of the masted broadside pattern, like the *Warrior* and our earlier ironclads, or whether the turret vessel is in future to be the only kind of protected ship. Our readers are probably aware that for several years no armoured ship of the first-class has been building in our dockyards, and those who possess faith in them are naturally growing indignant. At the same time, arguments which in past years proved delusive, and suggestions that have been tried and found wanting, are again being brought forward by those ignorant of the exhaustive trials already made at Shoeburyness, and but for the photographic records of these experiences the country would in all likelihood be asked to be at the expense of going through them once more. Fortunately, the War Department has a photographic establishment charged with the execution of records of this kind, among other work, and this department is enabled to bring forward the necessary proofs. We believe that the Woolwich Photographic Establishment, which, as our readers know, is under the charge of Mr. Baden Pritchard, has for many years past printed its work in permanent pigments, and, with the exception of Mr. Swan himself, was the earliest in this country to adopt for regular work the carbon process. Since 1869, when carbon work passed from the experimental to the practical stage in Mr. Pritchard's establishment, pigment prints have been annually produced in large numbers, and probably 100,000 impressions, for the most part of large dimensions, have been issued by the War Department to the several departments and officials entitled to receive the same. A branch of the Woolwich Establishment, consisting of a sergeant and gunner of the Royal Artillery, is stationed at Shoeburyness on purpose to be on the spot to photograph the results of experiments with guns and iron plates, and the records so secured are afterwards printed in carbon, and distributed, this work being done at Woolwich, where the negatives are stored. It was some of these pictures to which the attention of the Society of Naval Architects was recently called. The question whether the walls of a ship built in a certain manner, with armoured plates disposed after a particular plan, would suffice to keep out projectiles from heavy guns, was at once answered by a series of these War Department photographs. The various targets (each of which represents the side of a man-of-war) are shown first of all from the back, front, and side before it has been fired at, so that its construction may be thoroughly viewed, and afterwards we see the same target after it has been ill-treated, more or less, by projectiles. Photographs at once show how much damage has been done. Whether it is but a bolt sprung or a rivet fractured, or whether the shot has had the effect of letting the daylight through, the camera records the injury with the strictest impartiality. Everybody is ready to take the word of the camera, whether it is the constructor of the target, or the maker of the gun. The picture is as good as if the judges were looking at the target itself. It would be different if a draughtsman were employed; he might be prejudiced. Were he engaged by the inventor of the target, or the manufacturer

who had an interest in the character of the armour plates, he might always be suspected of subduing or ignoring injuries, or, on the other hand, the damage might be exaggerated. But photographic records executed in this straightforward way by Government officials are above suspicion, and it is certainly well that they are now produced in permanent pigments, that their value may thereby become enhanced.

Obernetter's Chromo-ColloTYPE Process.—Herr Obernetter has been experimenting, and with some success, apparently, for the purpose of doing in collotype printing what is done in chromo-lithography. We are glad to see that Herr Obernetter, in thus making known his process, has done so in a perfectly straightforward manner, and does not, like many others, talk about having accomplished the problem of "photographing in colours," a claim put forward by many who have done far less than he has in this direction. Herr Obernetter's effects are simply directed towards doing, as we have said, the lithographer in colour does. He gets his coloured picture by so many printings; he has as many lithographic stones as he has tints, and the finished impression is obtained as soon as the sheet of paper has been printed by every stone in the series. Herr Obernetter, instead of stones, employs several colloid films, from which he prints. These colloid plates are produced from negatives obtained from the original by his dusting-on process. In making these reproduced negatives, various degrees of exposure are given, according to circumstances. Thus a short exposure, and much working up with the plumbago, would furnish an almost black-and-white negative, and this, printed upon a colloid film, would permit of heavy colours being used, such as would be required to give very dark shadows; while, on the other hand, a delicate negative, produced by over-exposure and the use of very little plumbago, would yield a colloid plate to be employed for printing-off delicate colours. How many intermediate plates there should be, as well as the nature of the colours to be used, are matters, obviously, to be left to the discretion of the printer.

The Influence of Amateurs.—Great Britain has always led the way in the matter of dry plates and landscape photography, whatever may be said on the subject of portraiture. Whether it is that we have a larger body of amateurs in this country, or our own workers are more diligent, it is certain that progress in the matter of dry plates is due to British photographers. The gelatine emulsion process, originally brought forward by Messrs. Sayce and Bolton, has of late fallen into such good hands in this country, that we have secured dry films far more sensitive and trustworthy than any yet known. Both in Paris and Berlin, and, we believe, also in Vienna, gelatine emulsion plates as made in this country have been spoken of with much enthusiasm, and manufacturers in this country have been called upon to supply them abroad in goodly quantities. A year or two back it was impossible to obtain commercial dry plates on the Continent, except they came from this country, and it may still be the same, for aught we know. The reason for this is our large body of amateurs, many of the wealthy class, who are ever willing to make experiment and to further the art as much as possible. Our amateurs, indeed, have contributed in a vast degree to the recent processes, both of collodio-bromide and gelatino-bromide, while at the same time their number is so large that preparers of new plates always find a ready market for their wares. As our readers know, the Photographic Society of Great Britain has among its members a vast number of amateurs, the true professional element being altogether in the minority; whereas abroad the backbone of photographic societies are professional photographers. Again, it is well known that in this country manufacturers do a very large business with amateurs, for among well-to-do families dilettanti photographers are very frequently met with indeed.

Correspondence.

STATUS OF PHOTOGRAPHERS.

DEAR SIR,—After an experience of nearly twenty years, I cannot think that photographic assistants ought to be thought so lightly of as in your foot-note to A. S. Watson. Taking the number that are employed, and the number of easels that have been reported in the PHOTOGRAPHIC NEWS since its commencement, I think they will compare favourably with any other class with the same amount of remuneration.

I most cordially agree with A. S. W. that your correspondent of twenty-two years' experience is very much to be pitied. As regards being ungrateful or dishonest, perhaps having a notion of commencing in business for himself is considered being ungrateful; and then as to dishonest, why I can name three assistants of one employer, who can bear me out, that because it got in their employer's head that they were about to commence for themselves, he did his utmost to bring them in as dishonest without the slightest shadow of a cause; so that employers themselves are not blameless. This case I can vouch for the correctness of. Only one out of the three was intending to commence business, and all the three were in succession.

I am an employer myself, and have been for some years, but was formerly an assistant, so that I could not resist addressing myself to you in defence of my late fellow-assistants, knowing the case I quote, and its correctness. A SUBSCRIBER FROM THE FIRST NUMBER.

PS.—When I mention assistants, I do not allude to glass positive workers from the watering-place, who often give one a call at the close of their season.

[We quite agree with our correspondent that the status of photographers ought not to be so low as by some it is held to be. As a profession, photography requires exceptional skill and intelligence, and should stand high. All photographers are concerned in maintaining, personally and collectively, the legitimate status of the profession.—ED.]

REVERSED NEGATIVES.

DEAR SIR,—In the NEWS of the 21st ult. Mr. Dallas states that in 1863 he was the first to suggest the method of reversing the sensitized glass plate to produce reversed negatives.

The method was described in the *Photographic Journal* of October 21st, 1856, by Mr. Worden, Newcastle, for the production of non-reversed glass positives. I took a number of non-reversed positives about that time, and the only care required was to rub the glass dry with tissue paper, and push in the lens the thickness of the glass. J. L.

HOW TO BUILD A CHEAP AND EFFICIENT STUDIO.

DEAR SIR,—Permit me to thank Mr. Bridge (and yourself) for pointing out the insecurity of the "bridge" I erected for the safe passage of the "cheap studio question." At the time I built mine (I put up two, one side light, and one of the tunnel pattern, to give them both a fair trial), I was residing some five or six miles from Manchester, and just, as I believe, outside of several "boundaries." At all events, I was never troubled in the manner suggested, and I must candidly confess that I omitted the view of the question entirely. Since then, however, I have removed to a Yorkshire "linen" town, and find my "linen," *alias* my "shirt," is pretty considerably out at the "shifts." I am put to to circumvent

those public luminaries ye Borough Surveyors, Sanitary Inspectors, &c., in the matter of a small cottage I contemplate building, and in which I want to "fix" a room in the clouds with sufficient light to continue my "necromantic" experiments, and I can, therefore, thoroughly appreciate the difficulty. However, it seems to me that by making the "wooden" part of iron (galvanised and corrugated), we may get over the aforesaid individuals after the proper deposit of plans, notices, &c., &c., and the expenditure of a little red tapified circumlocution; and as I very nearly might have led some of our friends into a mess, I will, if desired, prepare and send you designs or estimates of such, seeing that I dabble somewhat in most trades, and very often "burn my fingers." My last "burn," however, I saw-sawed-in in the end of my right forefinger (before I had time to see where I put it) with a little circular saw I had just fitted, with an idea of making a very simple camera-back, &c., and this "split" has for the present so damaged my working powers that I feel constrained to apologise for the trouble I am about to cause yourself and compositors in reading this scrawl.—Yours particularly,
RICHARD PARR.

[We shall be glad to see the designs in question. It may be important to mention that whilst corrugated iron would meet the spirit of the Building Acts generally, it would not meet the letter in which brick or stone of a given thickness is mentioned. Hence the importance of consulting and "getting over" the District Surveyor.—ED.]

DANGEROUS PRACTICE.

DEAR SIR,—Pray allow me to warn your readers not to attempt to heat alcohol by putting it in a "Winchester," and standing it upon a hob, as recommended by Mr. Kay in the current number of the PHOTOGRAPHIC NEWS. Although that gentleman may have done what he mentions with impunity, he is to be considered extremely fortunate in having escaped a serious accident. Were the bottle to break whilst on the hob (which it is most likely to do), and three pints of alcohol find its way to the fire, it were only natural to expect most disastrous results.

The safest plan for heating alcohol is to place the bottle containing it in a large saucepan or other convenient vessel, containing water slightly warm in the first instance, and, after about five minutes, changing the water for some of a higher temperature; repeating the change of water, each time rather hotter, until the alcohol is sufficiently heated. There should be room in the bottle to allow for the expansion of the spirit, and the stopper should be kept out during the process.

The methylated alcohol usually sold *boils* at about 175°F., far below the boiling point of water.—Yours, &c.,

R. PEARSON.

COULD A WINTER'S LIGHT BE ARTIFICIALLY PRODUCED?

DEAR SIR,—Many of your readers will doubtless say we have had enough of that kind of light already. Very true, if it is the wet process they are working; but can the same be said by those using the bromo-gelatine plates? From what I have been able to gather, it is, I think, to say the least, doubtful.

When we remember, first, that portraits have been taken on dull days in winter, when it would have been madness to have made the attempt by the wet process; secondly, that the exposure required for gelatine plates does not appear to decrease in anything like the same ratio in which the light increases, it is, I think, a question well worth a little consideration. Not only this, but it was stated in these columns that the same kind of plate actually worked slower in a bright than it did in a dull light. If, then, this

be a fact, or even if we cannot get the extra rapidity we would naturally or theoretically expect when we have an extra amount of light, there must be a screw loose somewhere; and I think it would be well for those working the process to try and find the true cause, and, if possible, a remedy for this photographic paradox, if I may coin the word. If it is only fancy, let it be proved so; but if otherwise, let us try to do something to utilize the extra light which would be, in that case, lost.

Mr. H. Cooper says (see *PHOTOGRAPHIC NEWS*, Jan. 24) that the newest and most sensitive gelatine plates which, in a good light, may be five times as sensitive as a good average wet plate, require in a dull light an exposure of only one-thirtieth or less what the wet plate would need. Here Mr. Cooper gives an effect: what can be the cause?

Capt. Abney says (see *PHOTOGRAPHIC NEWS* for March 21):—"Now, with the gelatine plates, the yellow rays were of actinic use, hence the value of these plates in winter; but when the summer came, he did not think there would be that remarkable difference between the two which some anticipated." Capt. Abney gives us a cause. Yellow rays, then, are of actinic use; or, at all events, the blue are, according to this, of secondary importance.

Now, the question I would ask is, if a different kind of light is really required for bromo-gelatine plates, does the intensity of such light remain stationary, while that useful for wet plates increases; or is there the same increase in both? If the former, why is it not always possible (other things being equal) to get negatives with the same exposure? And if the latter, have we not still more reason for thinking we ought not only to get them with the same exposure, but with less; i.e., if the light is (say) thirty times as strong now as it was in the winter months when wet plates were nowhere, is it proved in practice that we can give thirty times less exposure and get the same result? It seems to me something like a man putting more money in his pocket, the said pocket having a hole in the bottom; but he can't fill it—the hole neutralizes the effect the extra money would have. Would it be saying too much to say the extra blue rays neutralize the effect we would naturally expect from the extra yellow rays which Captain Abney says are of actinic use?

Leaving out of the question for the moment what Mr. Cooper has said, we cannot be blind to the fact that in the race for rapidity the distance between the exposures required for wet plates and that wanted for gelatine is far less now than it was (say) in December; or, in other words, gelatine plates are not so far ahead of the others as they were.

Let it be given, then, that the yellow rays are the principal ones which do the work in winter. Surely we get more of those rays now? As I understand it, white light is made up of or contains all the colours of the solar spectrum; that if any colour were absent, the light would not be so pure and white; therefore there must, I think, be more yellow rays in the light we get now, or it would not be so white, as there are now extra blue rays. But the fact stares us in the face that the gelatine plates do not increase in rapidity in anything the same ratio as those prepared by the wet process. Is it because in winter the light is filtered through a yellow atmosphere which only allows the gelatine plate light to pass, that exposures are comparatively quicker? And, as I said before, when we do not get a proportionate amount of work done by the extra yellow light, is it because the extra blue rays we also get neutralize the peculiar light, or rather neutralize the effect such light would have upon the bromide films? If this is so, my idea is to keep back the light which is not only useless, but may be a hindrance, by colouring the glazed portion of the studio with a suitable varnish, so that the light on reaching the sitter would have been filtered through a kind of yellow glass, instead of (as in winter) through a yellow atmosphere. If the extra blue rays really do interfere, I think my suggestion of altering the colour of the light in the studio will prove a cure. Or

it might be managed easier by placing some coloured medium in or near the camera, so that the light reaching the gelatine film would have been filtered from the light not required for these plates, and which may do more harm than good by preventing the whole of the yellow rays from acting upon the plates. If, however, it can be shown that in practice the rapidity increases in the same proportion as the light, I, in common with others, will be only too glad to find our fears were groundless; for I take it that the shorter the exposure, the better both for photographers and their patrons.—Yours truly,
E. C. MURRAY.

THE USE OF DRY PLATES IN THE STUDIO.

DEAR SIR,—I am glad to find that Mr. William Green, of Berwick-on-Tweed, has been drawn into the ranks of those who are willing to give to others the benefit of their experience. This will afford me the opportunity of doing justice to Mr. Green. Some of the first dry plates showed signs of frilling, and it is to Mr. Green's suggestion that we owed the remedy. This letter is valuable also, because he gives us further evidence of his experience. It will prove useful information to many that, with well prepared dry plates, the alum solution can be dispensed with. Reduced to the two simple operations of developing and fixing, I have no hesitation in supplementing other statements made previously on this subject, and in saying that dry-plate work is not only much simpler, but also much easier than the old method.

It is gratifying to find that other statements are endorsed by an artist who has had nearly twenty years' practice. Mr. William Green uses the ferrous oxalate developer, and he must be well satisfied with its properties, since he is bold enough to say that he can obtain results far superior to what he did with the old process, his long experience of the latter notwithstanding. I am happy to be able to corroborate every word of this, and other assertions made by Mr. Green; and I wish further to do him the justice of stating that I believe him to have been the first to abandon the silver bath altogether. Mr. Green will not object to find his legitimate claim so frankly recognised. All new problems, and their successful working out, must be the source of satisfaction to those who will be at the pains of studying them, and they are often rewarded by almost unlooked-for results; I believe it to be the case with the use of dry plates in the studio.

In the matter of new ideas and new modes of working, which would seem to be very distasteful to the "stand-still" or "rest-and-be-thankful mind," I may be permitted to state how the workers of the chromotype process were sometimes met by those who shrugged their shoulders and expressed themselves so opposed to all those new-fangled ideas. So it must have been when first collodion was spoken of, and many other things of daily and indispensable use. We know that time, which tries all things, even dry-plates, always settles all questions by its inexorable laws; but for all that, there are minds which will investigate the new, although it may sometimes prove unprofitable.

We have had nearly six months of a most severe and especially dark winter, which must have taxed the equanimity and ingenuity of many members of our profession. Necessity, always the kind mother of invention, has suggested artificial light to some, and others have thought of quick dry plates, not caring to turn night into day. These are things for which most must be thankful, and should have experienced a certain amount of pride at finding that photography was not to be entirely baffled in its efforts. Both artificial light and emulsion plates are within the reach of all; no patents stand in the way of their use; but both require the expenditure of a little time and study.

These valuable additions to our knowledge considerably increase our means of locomotion in these fast days of telephones, microphones, and photophones. It must be a pleasing reflection for the follower of the camera to find that his art-science, which has been described as the most wonderful

invention of the age, has in store so many bright and interesting marvels, and it is to be hoped that they will not prove too dazzling.

Before stating that I remain as one always does at the bottom of a letter, may I express the hope, Mr. Editor, that Mr. Green's example will be followed by some more of our friends?—Yours, &c.,
C. FERRANTI.

PORTRAITS BY GASLIGHT.

DEAR SIR,—As photography by artificial light is just now on the *tapis*, I availed myself on Thursday night last of an opportunity of trying the actinic properties of coal-gas upon a wet plate. The occasion referred to was the exhibition, in the Art Gallery of this town, of a number of gas-burners by Wigham, Sugg, Bray, and others. The light I chose was Wigham's, consisting of 28 burners, and described as giving a light equal to 400 candles. My first plate was exposed upon a statuette; but as the light was erected upon a pillar some 10 feet high, I had not, of course, much power in the use of reflectors, nor could I place the figure in the best situation. However, as my object was to ascertain the actinic power of the light, it answered the purpose. The exposure was eight minutes. As all concerned in the exhibition were by this time very much interested in my experiments, and aided me by lowering the position of the light to about 5 feet from the ground, I determined upon trying a portrait from life, and by the use of powerful reflectors I so threw and dispersed the light that I not only obtained good modelling, but reduced the exposure to four minutes. Prints from each negative I submit to you. I used the wet process in the best and most sensitive condition known to me.

In regard to the cost of the gas consumed by this burner, it is very trifling—something less than twopenny an hour—so that whilst an exposure of four minutes is of course practically out of the question for portraiture, yet by using more burners a rapid exposure might be obtained with little expense.—I am, sir, yours truly,
P. M. LAWS.

ARTIFICIAL LIGHTING.

SIR,—I must really take exception to the paradoxical letter of Mr. Vincent Hatch in your last week's journal. He is adverse to the introduction of artificial lighting, inasmuch that it is a degradation to the art of photography, and is profuse in his allusions to a "respectable high-class business," "first-class photographer," "art portraiture," "legitimate work," &c. Is it really "legitimate work," and consistent with any "respectable high-class business," to practise any of the series of ingenious little devices which Mr. Vincent Hatch advises as the means of what he terms "hooking a customer"? He is surely a greater adept than myself if he can by any means "secure a deposit" from his customers; and as to "showing them a positive," do I again pervert the meaning of Mr. Vincent Hatch when I say that I have never yet had occasion to take *glass pictures* for my customers, or to resort to the so-called *positive work*? I am, moreover, convinced by his letter that there is something in a "photographic portrait business" far more degrading than "taking portraits by artificial light."—I am, sir, yours truly,
R. V. HARMAN.

SIR,—At the meeting of the South London Society on Thursday last, in the discussion on "artificial lighting," an interesting anecdote was related by Mr. Jabez Hughes, who said that many years ago he had been photographed by artificial light while at some meeting, and his portrait was immediately thrown upon the screen by the magic lantern. Mr. Hughes must have felt excessively flattered with the diabolical representation of his good-humoured and smiling countenance. We do that kind of thing now with the aid of a transparency, and the effect is considered somewhat better.—Yours,
R.

ARTIFICIAL LIGHT.

BY A. CLARKE.*

If the learned Dr. Drinkwater had to apologise on the subject of artificial light, how much more ought we to do so, especially as now the various members of the profession have enjoyed the privilege of reading his and Mr. Harman's papers on the subject? Fortunately for us, the "title" that our mutual friend, the Secretary, has chosen for this paper is a very wide one, and to begin at an early date, we find the first instance of a light other than the sun and moon about 1,900 B.C. (Gen. xv.).

We, who are so highly favoured in respect to artificial light, find described in novels of so late a date as those by Charles Dickens full descriptions of that "imp," the link boy; while in Russell and other kindred squares close by are still to be found the extinguishers used for putting out the links. Who has not read of the old watchmen, familiarly called "Charlies," with their horse lanterns?

These two instances will suffice to illustrate the progress made in artificial lighting during the last forty or fifty years; and when we contrast modern civilization with the above two pictures, or with the uncivilized life of our forefathers, we must own that all the arts which minister to our wants and conveniences we owe to inventors. But for them we should still paddle in canoes, paint ourselves blue, and so—as *Punch* says—promenade the parks. We should cover our floors with rushes, and go to war armed only with bow and arrow. And as for travelling, it certainly would not be with the speed of the "Flying Dutchman," or the convenience of the underground railway. It was left for Winsor to utilise coal gas for illuminating purposes, and it is recorded that he worried the town for three winters before he could attract any serious attention to his views.

The subject of artificial light for photographic purposes has of late received much attention, although there appears to be great difference of opinion as to the advisability of its use, even while admitting its perfect success in the way it has lately been employed. Some persons object on the score that it would unduly lengthen the hours of labour, and that photographers have enough to contend with in their daily struggles during the usual hours without having to work after dark. But its employment at night is only *one* of its uses, though a very important one, as in cases of which I shall speak presently. The importance, however, of having an apparatus capable of giving perfect results always ready to hand places in the hands of the photographer the power to take pictures whenever he chooses, irrespective of weather, and the importance of this application can scarcely be overrated. Certain it is that there are numbers who have been much pleased with the means which has enabled them during the late dull season to have abundance of work to do, and who would not willingly now be without such a valuable adjunct to the studio; and it is useless for people to object to the introduction of any appliance which puts a new power into the hands of photographers, and conduces to their convenience and benefit, simply because it may be abused by some.

A great deal has been written on the subject of artificial light lately, and in some cases by persons evidently with little practical knowledge, who seem to possess the art of creating shadows and lending existence to what does not exist. One writer, who judiciously conceals his name, and uses a *nom de plume*, says, in last week's NEWS, that the characteristics of all the portraits he has seen taken by artificial light are "unnatural and waxy skin, glassy

* Read before the South London Photographic Society.

eyes, false and reflected lights, black shadows, and the entire appearance very supernatural and corpse-like." He says at the commencement of his letter that he is in the habit of perusing the NEWS, therefore he might at least have supposed that it was a different class of picture to what he describes of which the Editor says—"There is nothing to distinguish them from ordinary good work by daylight." The same writer also says that taking the cheaper method than the electric light, viz., the luxograph, it will run the photographer to £40 or £50, and that it will take many sitters to reimburse that outlay. Practical men have found that they have cleared the cost in little more than a week, and in one case I have to speak of this evening, the probability is that the cost will be cleared by the one evening's work, and those must unquestionably do good service to photographers who point out and practically demonstrate new departures from the usual routine. To one of these "new departures" it is my desire to call your attention, and it has the recommendation of being a very profitable one; for, while giving one's attention to its photographic and artistic aspect, the satisfactory character of its pecuniary phase is not to be despised, even by those who object to working "after the usual hours." The hours during which a series of about 120 full-length cabinet pictures can be taken at a fancy dress ball are certainly very unusual, though they scarcely come under the condemnation of those who object to working in the evening, as the greater number are taken during the earliest hours of the morning.

The firm to which I belong has now had sufficient practical experience to be enabled to speak decidedly on the success of what, until lately, was only a matter of speculation, namely, the possibility of taking the apparatus and using it in an apartment adjoining a ball-room, and of taking a large number of pictures while the ball proceeds. I imagine that few will dispute as to whether this use of artificial light is not both a gain and a convenience in every way—not only to the sitters themselves, who are spared the trouble of dressing and going to the studio (which often prevents many from being photographed who would otherwise do so), but also to the photographer, who thus secures a large number of sitters, and adds considerably to his celebrity.

Our experience shows that the greater portion of the company on the occasion of a ball in fancy costume gladly availed themselves of the opportunity of being photographed when it is unattended with the usual trouble involved in dressing purposely. By the plan which we pursued in taking the pictures on the first occasion at Chelsea (and which has again been most successfully carried out last week on a similar occasion), we were enabled to take about 120 half-plate negatives in about six hours, this giving an average of three minutes for each sitter.

Of course it would have been impossible to do this by the wet process. The plates we used are known as the "London gelatine emulsion," and were in every way satisfactory. We used a changing-box holding twelve plates. One person posed and arranged the sitter, another assistant being at the camera to focus and remove the dark slide to another, who changed the plate while the next sitter was arranged, and the Luxograph, by which instrument they were lighted, was attended to by a youth. In this way everything went on with the greatest smoothness and celerity, and from the extreme rapidity of the plates, which only required three to five seconds' exposure, there was little chance of any sitter moving, and all were much pleased at the rapidity and novelty of the affair. I have brought a number of the pictures for your inspection. I should state that only a plain background was used, the fancy backgrounds being added by double printing, as there would have been no time to change the backgrounds.

I have not thought it necessary to say anything re-

specting the development, &c., of the plates, as such ample information has been given by Mr. Bennett and by Messrs. Wratten and Wainwright, who manufactured the plates we used; but I trust I have said sufficient to show photographers that there is a field open for them on similar occasions to the one I have described, and also at many large public and private gatherings, such as bazaars, coming of age, &c.

The Luxograph is easily placed in a drawing-room at any convenient spot, and there is not the slightest smell, fumes, or any inconvenience arising from its use; so that on occasions where many sitters would be photographed were it not for the trouble of going to the studio, the best way, both for their pleasure and convenience and the photographer's profit, is to take the studio to them.

Before concluding, we draw your attention to the main advantages to photographers of the two systems now patented, viz., the Vanderweyde and Luxograph. Neither requires a secondary light, but both give perfect results in lighting the sitter, and there are no black shadows to be overcome. We consider, and justly so, that our system gives equally as good results as the electric light, and at a very much less cost.

The ease and simplicity with which a picture can be obtained, either with a wet or dry plate, is something delightful. Dr. Drinkwater says, in his paper lately published:—

"I find that the electric light is far from constant. I have seen most of the methods in use, and they all flicker in a marked degree. The light is sometimes strong and it suddenly becomes weak—at one time white, another red, and on more than one occasion I have seen it, after changing from white to all the colours of the spectrum, resolve itself into darkness and refuse to emit light at all."

Respecting the electric light our experience has been considerable, and we have had unusual opportunities of ascertaining what is necessary for its successful use in portraiture. For this purpose photographers must recollect that the bare light is of no use whatever, but must be used by the Vanderweyde or other systems. Various writers have put down the cost necessary for the above at about £200 to £700; but it will be found that the largest cost will be entailed if satisfactory apparatus is to be purchased.

A great deal has been said respecting battery power, but at present it is of no practical use for portraiture. The light is to all appearance actinic and brilliant, but the result on a plate is most disappointing, even with two minutes' exposure, with everything not only in first-class order, but with the best of apparatus. Even should important improvements render a battery available, few would care to go through the trouble and mess entailed in filling and emptying the cells, especially on a cold winter's night, with a good north-east wind blowing, for the battery must be kept out of doors on account of the fumes.

I believe that I am not out of order in saying that the author of the preceding paper can say something about the use of batteries. The albo-carbon we have not seen, but we were lately informed by a photographer of experience who has used it that it is of no practical use for portraiture. We are convinced that the pyrotechnic light, used in a suitable manner, is the most actinic form of artificial light available for portraiture, and we find the exposure required by the luxograph seldom exceeds fifteen seconds for a perfectly exposed negative, while the cost of the compound is so small as to be of little consideration, being about 2½d. or 3d. with the usual wet process, and under 1d. when rapid gelatine plates are used.

ASBESTOS POWDER AS A CEMENT.—Asbestos powder made into a thick paste with the liquid silicate of soda is stated to be found of great advantage for making joints, fitting taps, connecting pipes, and filling cracks in retorts.

A PHOTOGRAPHIC PARADOX.

A CORRESPONDENT, whose letter appears on another page, asks a question which at first sight will probably cause a smile. Mr. Murray asks, Is it possible to create a winter light artificially? In short, Is it possible, in the bright light of summer, to reduce the studio to the murky conditions of (say) November? Odd as the question appears, it seems to arise very naturally out of a consideration of the subject discussed in his letter. The common experience of workers with rapid gelatine plates points to one very singular fact, namely, that these plates are relatively much more sensitive in a dull light than in a bright light. To take the illustration given in a communication by Mr. Cooper, if a gelatine plate exposed in a bright light require only one-fifth of the time required by a wet collodion plate, the same plate would in a dull light require only one-thirtieth of the time required by wet collodion. This is startling enough, and the more so that it is opposed to old dry plate experience. It used to be an axiom that dry plates were almost useless in a very dull light, being singularly insensitive to weak radiations. When Dr. Hill Norris issued his rapid dry plates, which were in their day a marvel of sensitiveness, he cautioned photographers that it was useless to expose them in dull foggy weather, as they appeared to be almost insensitive to dull yellow light; whilst it is in just such light that gelatine plates "come out strong," as Mark Tapley would have it. But if dull yellow light answer best for these plates, shall we, and can we, create such conditions in summer? is very naturally asked. Or, as some will put the question, are gelatine plates actually more sensitive to yellow light, or are they only relatively so? As the gelatine plate gradually loses its superiority over the wet collodion as the light grows brighter, is there a point at which the wet plate will equal or surpass its dry competitor? We do not intend to discuss the subject here, nor to offer an *ex cathedra* answer, otherwise we should say it was purely a question of relation, and that the gelatine which always retain its lead.

We put the question as our correspondent has raised it, and shall be happy to receive the views of men of experience on the subject. At any rate, it suggests to experimental photographers who have wisely adopted the use of gelatine that it will be wise to avoid being too hasty in throwing away baths, &c., which may prove useful in summer.

PHOTOGRAPHED NOTORIETIES.

SOON after the advent of the *carte-de-visite* mania, something under twenty years ago, a vigorous writer made the remark that photography—or, rather, the phase of it then

under notice—had created a new passion in the human breast, the passion for seeing or possessing the image in little of everyone who possessed the remotest possible claim to celebrity, popularity, or notoriety. That passion has been steadily growing. All that was beautiful or noble having furnished food for the camera, that which was repulsive was next made to contribute to this new form of iconolatry! The grand head of a philosopher or poet gave place to the hideous repulsiveness of a Peace!

At once attractive, interesting, and instructive, the extensive circulation of portraits of distinguished persons has certainly had an educational value. As some have alleged, the education has been of a democratic nature, for certainly photography is a great leveller. It has been found by the vulgar many that kings, queens, and princes are very common-place looking persons, often excelled in physical charms by the most humble citizens; but still the general effect was of a civilizing nature, and beneficent in its influence. Occasionally there have been outcries against the publicity and popularity given to some fair anonyma by the extensive circulation of a charming portrait, or protests from some against décolleté portrait of some burlesque actress; but, as a rule, photography, considering circumstances, has been marvellously free from vulgarity or offence against good taste. A protest in a contemporary calls attention, however, to a form of offence which deserves some consideration. A well-known graceful essayist in the *Sunday Times* says:—"The Zulu war is bad enough, but it cannot be helped; but why we should have Indian photographs of ungainly Zulus, almost in a state of nudity, exhibited in our shop windows, it is impossible to say. If these had been photographs of well-formed English people, I imagine some one would have immediately interfered to prevent their being shown."

We must confess the same question has often occurred to our own mind. Why coarse and nasty nudities of repulsively low specimens of humanity should, because of some ethnological interest, be tolerated as decent, when similar portrayals divine of a beautiful and graceful person would be regarded as a fit subject for the attention of a society to repress vice, we cannot understand. By all means we should let the law interfere to repress everything naturally repugnant to the spirit of decent society, but there should be consistency in such action. We fear, however, that the real evil is in the morbid taste of the public which makes a possible market of ugly nakedness. It is the demand which creates the supply, and so long as some portion of the public require offensive portraits of half-clad savages, they will be supplied. We do not see any remedy; but we confess we wish photography were not responsible for some of these breaches of good taste.

PORTRAITS BY GASLIGHT.

WE print a letter on another page, in which the possibility of an altogether novel form of artificial light for portraiture is pointed out. Mr. P. M. Laws, a portraitist of Newcastle-upon-Tyne, has been producing portrait negatives by the light of ordinary coal gas, the same which is used in street illumination, and with a degree of success which is marvellous. An exhibition of various ingenious gas burners, by skilful gas engineers, was held in the Art Gallery at Newcastle recently, and Mr. Laws availed himself of the opportunity to test the actinic value of gas. The light selected for trial was Wigham's, consisting of twenty-eight burners, and giving a light equal to four hundred candles. A wet plate was exposed upon a statuette, and, with an exposure of eight minutes, gave a good negative. But the position of the light was unfavourable for the photographic illumination of an object; and this having been remedied, Mr. Laws ventured on the exposure of a living sitter, the lowered position of the

light permitting the satisfactory use of reflectors. The exposure given was this time four minutes, and the result was very satisfactory. We have a print from the negative before us; the lighting is good, and the modelling excellent, nothing in any way suggesting the production by artificial light.

The cost of gas consumed is practically nominal, being at the rate of twopence per hour. What the first cost of the burner and fittings was we cannot say, but probably not very heavy. As almost every studio has gas in its immediate proximity, the cost of fixing the special burner, and using gas occasionally, cannot be very serious, and it involves no special inconvenience of any kind. Those who do not wish to enter upon night photography may find such an additional appliance a valuable supplement to the dull light of a November afternoon.

As Mr. Laws very aptly remarks, an exposure of four minutes is out of the question for ordinary portraiture, but an increased number of burners would reduce the time. Further, Mr. Laws used the wet process, which, according to daily increasing testimony, is many times slower—especially in comparatively dull light—than the rapid gelatine emulsion plates. It is quite possible that where the wet collodion plate required four minutes, a dry gelatine plate might have required less than one minute—might, in fact, have brought the exposure within fairly practical limits. We hope that these experiments will be followed up, as from the excellence of the first examples we are satisfied that results of practical value may be obtained with less inconvenience than is possible by most kinds of artificial lighting.

FRENCH CORRESPONDENCE.

LECTURES ON PHOTOGRAPHY AT VARIOUS INSTITUTIONS IN PARIS—NEW WORK BY M. RADAU ON THE APPLICATION OF PHOTOGRAPHY TO SCIENCE—CONDUCT OF THE MONITEUR DE LA PHOTOGRAPHIE UNDERTAKEN BY M. LEON VIDAL.

Lectures on Photography in Paris.—Public opinion in Paris appears lately to have taken a turn in favour of the spread of, and (what is still better) of education in, photography. This may be taken as a good augury for the science—at length permitted to count as such, and to emerge with honour from the state of disrepute in which endeavours have persistently been made to keep it from its very start into existence up to the present. The reasons for this discredit are not far to seek, provided that we keep out of sight the rapidity with which photographic progress has taken place, and the discoveries which, though made by a few investigators only, have received that knowledge of a general kind belonging to the whole sphere of science. In the first place, there is no doubt that photography, marvellous as were the effects produced, was considered to be merely an application of well-known physical and chemical facts, but no important or practical conclusions were drawn from its results. When saying this, I must be understood to speak generally, for there certainly were among the forerunners in our art those who foresaw, and were bold enough to foretell, its development as we see it to-day. On the other hand, from the art point of view, though doubtless photography was accepted as a useful auxiliary to the fine arts, there were many who were so ill-advised as to go much in advance of the truth, and to consider it as a dangerous rival of the arts of drawing and engraving. "It's all up with art!" was a common expression with men frightened out of their wits at the bare possibility of arresting in motion and fixing a reflected image. Now we have turned our backs on these exaggerated fears, for they were merely the effects of sudden surprise; and we are able calmly to take the measure of what photography is able to accomplish. Very little reflection helps us to appreciate the immense services that photography can render—or, better still, is always rendering—to art to science,

and to manufactures, nor can we discover that in any way it is injurious to either of them. These truths, well known as they may be to the initiated among us, have still to be demonstrated to the world at large, and on this account we note with pleasure the efforts, worthy of all praise, that are being made to show to the public photography in its true form—the docile handmaiden, not the rival, of art and of science. To this current of popular opinion, increasing, as it does, in strength from day to day, is due the enterprise undertaken by the Scientific Association of France, who have appealed to our esteemed fellow-worker, M. A. Davanne, to deliver a lecture at the Sorbonne on the history of photography from its origin to its present state of development. Never hitherto has this temple of science been opened for the service of photography, and therefore the occasion referred to—Thursday, the 20th of March last—may be well regarded as an important epoch in the life of the newly-recognized science. Let me say at once that M. Davanne was perfectly equal to the difficult task he had undertaken; I have no hesitation in asserting this, notwithstanding the short time he could give up for preparation, and the immensity of the ground over which he had to travel. His object, as will be easily seen, was not to give technical instruction in photography, but only to follow step by step its march of progress, to show of what importance it is, and how numerous and valuable are the applications to which it lends itself. Possessed of great lucidity of style, and long experience in the art of experimenting, established, moreover, on ground which he had often traversed, and with which he was, therefore, perfectly familiar, M. Davanne succeeded in arousing the enthusiasm of his audience—and this is no small praise, for that audience was composed almost entirely of scientific men, among them some very distinguished ones; yet all, fascinated and surprised by what they have heard and seen, exclaimed with one accord—"What a beautiful thing is photography!" Nothing, moreover, had been omitted to further the objects of the learned lecturer: a series of admirably-managed experiments permitted him to demonstrate every argument that he employed, and to illustrate each phenomenon that he mentioned. Negatives were produced before the eyes of all present. He was able to prove the enormous sensitiveness of iodised collodions and of emulsions, though the meeting was held at half-past eight at night. By the aid of a yellow light ingeniously concentrated on the spot where plates were sensitized, and sensitive bodies were operated on while the rest of the hall was wrapped in profound darkness, he permitted the listeners to follow the minutest details; and finally, by means of a white light (that of magnesium was employed), he convinced them that a simple and extremely short exposure is sufficient to produce an intense image on the surface of a sensitive film. All the principal processes for taking positive prints were experimentally illustrated before the delighted audience. Among these were carbon prints obtained on different coloured tissues by the method of M. Chardon, of whose personal and efficient assistance M. Davanne availed himself on the occasion. Woodbury-types were worked in presses of the establishment of Leunereier and Co.; phototypes were pressed with fatty ink rollers by a couple of assistants of M. Berthaud; specimens of *Heliogravure* by the process of M. Rousselon, of *Heliochromie* by those of MM. Cros and Ducois-de-Hauron, of *Photochromie* by M. Leon Vidal, were shown in succession to illustrate the descriptions given by the lecturer. The numberless applications of photography to general science and to the arts, its use to the criminal police, its services in microscopic science, geography, ethnology, and astronomy, and its employment for the restoration of ancient manuscripts, were all rapidly passed in review, and the illustrations in turn were projected on the screen by the oxy-hydrogen light under the care of M. Molteni. The success of the lecture in general was unequalled, and the audience testified by continually renewed applause to

he satisfaction they had derived from it. It was felt that a new era would henceforth be open to photography, for its right to be admitted among the classified sciences had now been fully proved. Of that success M. Davanne may be most justly proud. That he anticipated great results was proved by his closing words, in which he expressed his regret that nowhere was there an opportunity for any one to receive instruction in all the beautiful things he had been showing. Photography, he said, is a noble science, but it is neglected because there is no technical instruction in it. In this he was perfectly right, but he probably forgot what is at present being done at the National School of the Decorative Arts, where this very session a course of instruction has been organized in reproductions of works of art for the manufacturing industries, and in this course, as may be imagined, photography will have a prominent place. To the intelligent and amiable director of this art school, M. Louvier de Lajolais, is due the realization of this idea, which will be found to meet fully the wants of technical instruction in photography. A similar scheme, no doubt, M. Davanne would like to see carried out in all the schools where instruction is given in applied science. Anything in praise of the course above-mentioned cannot be stated in this letter, whose writer is himself in charge of it. It is scarcely becoming to eulogise oneself, but I may be allowed to express an opinion that the example set by this important school of art cannot fail of being a fertile one. As a proof, we have the assiduity with which the lessons are attended, and the petition presented by the director to the Minister of Public Instruction that instruction of this kind may be introduced into the training institution. I am not aware of what is being done in England in this direction, and it may be that you are much further advanced in the path of instruction in the art of reproduction founded on the discoveries of photography and electrotyping; but in France we have still all to do under this head, and the reason why I insist so strongly on the favourable movement which, to the honour of photography, is just now taking place, is that all my fellow-labourers in other countries, where they may be afflicted with a similar need, may be encouraged to pursue the same path of progress. The first course professed at the National School of the Decorative Arts will also be the subject of a special work to be published for introduction into Fine Art education at the universities. In this work there will be found laid down a plan of the instruction, which, though doubtless capable of great improvement, may serve as a starting-point for those who desire on their own part to make attempts of the same character. The Central Union of the Arts applied to Industry have also organized a lecture to be delivered on 4th of April next, on "The Application of Photography to the Manufacturing Arts." Of this, in a future letter, I shall give an account; needs must that I shall be present at the meeting, as, to tell the whole truth, I shall have the honour of being the lecturer. All these lectures and lessons that I have now enumerated are a complete justification of the sentiment with which I commenced this letter, that public opinion is now very favourable to photography. We ought to be thankful for it, as well as for all that is capable of ennobling our art, and raising it in the scale of human science, and we should feel ourselves encouraged to do all we know to increase its usefulness and value.

New Work by M. Radau.—An interesting book, written by M. Radau, and published by the house of Gauthier-Villars, has just been issued from the press, in which will be found a complete corroboration of all that I have stated on the subject of the applications of photography to science. This work, whose title is "Photography and its Scientific Applications," is well adapted to promote the extension of photography of which there are at present so many signs. In his preface the author expresses his

astonishment that the numerous applications which photography admits of have been so late in introducing themselves into the practice of men of science; even now the attempts to do so are few and far between. He further cites all the applications to astronomy, meteorology, chemistry, physiology, &c., to prove that he is right in recommending scientific men to avail themselves fully of the services that photography can render. The examples of Mr. Warren de la Rue in England, and of M. Janssen in France, may excite, though they still wait for, imitators; and as progress is everywhere, and more especially among ourselves, excessively slow, we cannot sufficiently thank M. Radau for the labour he has undertaken, and hope to congratulate him on the result. He belongs himself to the ranks of men of science, and his authoritative voice cannot but have an echo. It will be seen, therefore, that we in France are at the present moment engaged in advancing the progress of photography, and all are ready to lend their assistance—some by word, others by writing.

The Moniteur de la Photographie.—I cannot finish this letter without announcing to the readers of the PHOTOGRAPHIC NEWS that the vacancy in the editorship of the *Moniteur de la Photographie*, which was caused by the death of the late lamented Ernest Lacan, and which I had filled provisionally since that event, will now be occupied by me permanently, the result of an agreement with his widow, who remains proprietor of the journal in question. It was some time before I could persuade myself to undertake this office, which I had hoped to see filled by one more able to do so worthily; but time was pressing for a settlement, without which there was some risk of imperilling the existence of the paper. My intention now is to devote all my energies and spare time to the work, with the hope that, should anyone present himself more capable of taking it up, I may be able to hand over to him both the editorship and the responsibility attached to it. What sustains me in undertaking this enterprise—which is, perhaps, too great for my powers as respects the knowledge that it requires—is the strong desire to make use of it in promoting the progress of photography. In this path I have been for a long time a traveller, and have, therefore, no fear of fatigue; but I have to pray for the indulgence of my readers and of my photographic colleagues for very possible shortcomings. In one respect they can materially assist me—namely, by sending me their valuable communications. I ought also to say a few words on the important work that I have now undertaken in connection with the PHOTOGRAPHIC NEWS, on whose staff I am about to occupy the place of my excellent friend, who was, up to the time of his death, the French Correspondent of your valuable journal. Having been for a long number of years the attached friend, as well as a colleague, of Ernest Lacan, it seems that I am destined to pay to his memory a real debt of affection by following in his footsteps—by putting my name, which he esteemed, in the place of his, which I shall never forget. Will the subscribers and readers of the PHOTOGRAPHIC NEWS charitably accept his successor, regarding me as an old acquaintance, for the majority of them know my love for the photographic art, and excising one whose pen is so weak, for venturing to take the place of a friend, now, alas! no more, but whose elegant and correct style was so highly estimated? I may, it is true, succeed him; but I have not the assurance to believe that I can ever replace him.

LEON VIDAL.

THE BEST PLAN IN THE WORLD TO TRIM PRINTS
Mr. J. IXALES, writing in the *St. Louis Practical Photographer*, says:—

"It used to be a tedious job, after a big day's printing, to set to work with a pair of scissors and glass, to trim up the

day's work before toning, to say nothing about clumsiness after it was done.

"My plan now is with a common steel die and mallet; fold a sheet of paper up into sixteen parts, and with two cuts the whole thing is done as 'true as a die.' It don't occupy more than one minute to trim thirty-two pieces. Cabinets are cut as quick as cards. The cost of the dies is \$5 for the cabinet, and \$4 for the card size. Then, I have different sizes and shapes of them for cutting out masks with perfect exactness and facility—a plan once tried, never can be given up.

The same writer also gives the following hints:—

"HOW TO MAKE AND KEEP THE SILVER BATH FOR PAPER.

Nitrate of silver	1 part
Nitrate of potash	$\frac{1}{2}$ "
Water	9 parts
Alcohol	3 "

"Empty this into the silvering tray, and leave it there for months, or years, if you wish. Before silvering take off the scum, which forms on the surface of the solution, with a strip of paper.

"This bath will keep in order for years, by simply adding to it more solution prepared as above. Should it evaporate too much in hot weather, it will be necessary to add water to it instead of the solution. This can easily be seen; when the prints begin to look coarse in the printing, the appearance they have with a too strong silver solution is very frequently taken for being caused by too weak a solution, and by strengthening it only adds to the disease.

"Float the paper from one minute to one minute and a-half; draw the sheet off slowly and over the edge of the dish; lay it down on a board and blot it thoroughly, surface dry, with blotting-paper. By this means you will never be troubled with tear-drops, or streaks from unequal drying, &c., &c. A sheet can be silvered at any minute in the day, when wanted in a hurry, and dried in less than five minutes, the solution always being ready in the dish. This bath has not discoloured with me in three years' use."

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held on Thursday evening, April 4th, at the Society of Arts, John Street, Adelphi, the Rev. F. F. STATHAM, F.G.S., President, in the chair.

THE SECRETARY read the minutes of the previous meeting, which were confirmed.

THE PRESIDENT begged to apologise for his absence from that meeting through illness.

In accordance with the motion at the last meeting, he had written a letter of condolence to Mrs. P. Le Neve Foster.

THE PRESIDENT then called upon Mr. A. Brittlebank to read his paper on Artificial Lighting which he illustrated with diagrams and experiments; he also exhibited a very simple changing box for changing the plates. The Chairman then sat for his portrait, the exposure given for each exposure (a double plate being used) being about five seconds, which was developed successfully, and handed round for inspection of the members. [Owing to the late receipt of copy, and the necessity of going to press a day earlier, to publish before Good Friday, we are unable to get the diagrams engraved in time for this week's issue. The paper will appear in our next.]

THE PRESIDENT next called upon Mr. Clarke (Messrs. Alder and Clarke) to read his paper bearing on the same subject—Artificial Lighting (see page 170).

THE PRESIDENT then made a few remarks on the two papers which had been read. He said he thought it a great stride in the right direction to take portraits independent of daylight, and considered it would be a great acquisition to many, especially during the dull winter months. The apparatus exhibited by Mr. Brittlebank had one special advantage, being very portable and very simple to construct at a very low cost. He thought

the magnesium light that Mr. Brittlebank used was too strong it being rather unpleasant to the eyes; but he supposed that could be easily overcome, and he had an idea that there were many other simple lights of great actinic power that might be used for the purpose, such as burning phosphorus in oxygen; and the light Mr. John Spiller exhibited a few years ago, burning sulphur or nitrate of potash, might be of great value; but with a lantern light, when used, it would be important to make the light comfortable to the sitter's eyes.

MR. JABEZ HUGHES was then called upon to make a few remarks on the subject. He said he would rather not at present, as he only came to listen; but he might do so further on.

MR. CLARKE stated that he had used gelatine plates for the ball at Chelsea, and also at another subsequently, with what success he would leave the gentlemen present to judge for themselves by the specimens he passed round (which were greatly admired).

MR. COBB had kindly assisted in developing some of the plates, and perhaps he might make a few remarks as to his mode of proceeding.

MR. COBB said he developed the plates, which were gelatine ones, by the ordinary method, which had been published many times, the only difficulty he had found, although the plates had received such a short exposure, being that most of them were over-exposed.

MR. PEARSALL wished to ask Mr. Clarke whether the negatives had been retouched, or only the defects touched out. He was very pleased with the results he had seen, and thought some of the specimens were almost perfection, and he also thought other lights would come forward.

MR. CLARKE, in reply, said that little or no retouching had been done, only the defects touched out. The negatives when taken had almost the appearance of being retouched. He thought the effect was due to the great penetrating effect of the light used, if he might so use the term.

MR. BRITTLEBANK stated that one of the specimens he handed round was taken at eleven o'clock on the night previous. He had brought the apparatus up in its rough state, so that members could see, and make it for themselves if they thought proper; and altogether, he had not taken more than a dozen negatives with it, and many improvements might be made on it.

One or two of the negatives Mr. Brittlebank handed round for inspection were very sharp and clear, and fully bore out what he (Mr. Brittlebank) had said.

MR. BROOKS said that he had had little or no experience of artificial light as applied to portraiture, his work by artificial light being in another direction. He thought the combustion of phosphorus in oxygen could be brought into use, it being one of the most intense lights known.

MR. BRITTLEBANK said he did not think a reflector of parabolic form was required.

MR. HARRISON did not quite agree with Mr. Brittlebank in some of his remarks about the reflector used. He said reflectors might be made with copper, and well cleaned, and then rubbed over with nitrate of mercury, which would be far less expense than silvering, as silver did not last any time; but with the nitrate of mercury it could be easily applied at any time, and answer every purpose.

MR. BOLAS said he did not think it mattered much whether the reflectors were square or round, when a diffuser was used, but a parabolic form was the best when the light emanated only from a point, but not where a row of lights was used, as in Mr. Brittlebank's arrangement.

MR. COBB said he thought that we were passing through a very eventful time in regard to photography. He thought we should soon see advertised, "no home without a camera."

In reply to a question,

MR. CLARKE said the cost of the light when a gelatine plate was used was about three-farthings each exposure.

MR. LAVENDER remarked that he had seen some specimens done by the electric light, which he considered perfect.

MR. CLARKE, in reply, stated that he had used the electric light, but found it was not suitable with his apparatus.

MR. W. B. BOLTON said Mr. Clarke's reflector was not suitable, as it required a parabolic form, hence his failure.

MR. JABEZ HUGHES said he had listened with very great interest to the evening's proceedings, and thought it was a difficult matter to deal with, in the sense of avoiding the question of shop which was often raised, and thought that gentlemen who had spent a great deal of time and money on these inventions or improvements were public benefactors, and were entitled to make the best market of their efforts, and that at the same time, at

societies, they could be discussed on their merits, without overstepping the limits of the Society. He thought we were now upon the threshold of a new era in photography, just about the same as when the old Daguerreotype process was going out, and the introduction of collodion, and the extraordinary feature was that we were now getting dry plates of marvellous rapidity, which should not be lost sight of; if we had not those rapid plates the results he had seen that evening could not have been obtained. Portraiture by artificial light was in itself nothing new, for about eighteen years ago he remembered presiding at a meeting, and having his portrait taken on the platform, before about two thousand people, by the electric light; the plate was next developed, and then projected on a screen by the same light, to the satisfaction of the audience. Mr. Cobb had been bemoaning that he could not that afternoon get a portrait by an ordinary exposure of twenty seconds. He (Mr. Hughes) said he remembered in the old days that he could only get portraits with twenty seconds' exposure about two months during the year; at other times it used to be 60 seconds, 90, and 120, and sometimes more; but with the extraordinarily rapid plates things were greatly altered, and he thought, after the summer had passed, we should see very great improvements in artificial lighting.

Mr. W. B. BOLTON exhibited some specimens taken by ordinary gaslight, 28 burners being used, equal to about 400 candles; they were taken by Mr. P. M. Laws, of Newcastle; one was a statue having had eight minutes' exposure, the other a vignette portrait, five minutes' exposure, showing that it was possible to take portraits by gaslight.

A vote of thanks was then passed to the gentlemen who had contributed to the proceedings of the evening, after which the meeting was adjourned to May 1st. On that evening a paper will be read by Mr. Foxlee, "On the Continued Action of Light in Carbon Printing"; also a paper by Mr. Harrison "On Reflectors."

The PRESIDENT said he wished to announce, before the meeting broke up, that it had been resolved upon in committee that evening, that as the Society had many surplus presentation prints of past years, they should be disposed of at the next meeting, and the proceeds applied to wipe off a small debt there was owing by the Society, so if any gentlemen had not had their presentation prints, they must claim them before that evening. He hoped soon to see the Society relieved of the little difficulty respecting finance. The presentation prints alluded to were the prints of three or four years back and previous, as none have been issued since about that time.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Society was held, as usual, at the Museum, Queen's Road, on Wednesday, the 2nd instant, Mr. W. RADCLIFFE in the chair.

The minutes of the previous meeting having been confirmed,

Mr. H. A. DANIELS (Hon. Secretary) apologised on behalf of Mr. R. Biggs for the postponement until the May meeting of the paper that gentleman was announced to have read. He (Mr. Daniel) then exhibited a changing-box for dry plates of the old pattern, which he thought would prove of interest, especially as one of the latest and most approved designs was to be exhibited during the evening. The old pattern box was simply fitted with a groove at the top to admit the dark slide, and with a shutter and sliding top. A metallic shutter, working on a hinge, with a milled-head handle, opened the dark slide.

Mr. BRIGHTMAN then exhibited a newly-designed camera by Mr. G. Hare, and pointed out the many advantages of this instrument over the ordinary form of portable cameras. By a novel arrangement of the base-board, the body of the camera can be extended from three and a-half to sixteen inches, and when extended is perfectly rigid in every part. The main base-board, being panelled, carries in a well fitting groove a sliding framework which can be instantly extended and clamped in the required position by milled-head screws; for the delicate focussing, the rack-and-pinion is then brought into play, this arrangement answering to the rough and fine adjustment of a microscope. By a simple arrangement of the back both vertical and horizontal swing motion is obtained; the front is also capable of adjustment in four directions. In addition to the usual rising front, by a simple changing of a milled-head screw the front can be lowered to any desired extent—a great advantage in taking

pictures from elevated positions. Mr. Brightman also exhibited (in case anyone present had not seen one) a seven by five changing-box by the same maker. The fine finish and smoothness of its working, as also its automatic simplicity, were exceedingly admired.

Mr. DANIEL said he could not help remarking that the camera was undoubtedly the best and most completely designed he had ever seen, everything that could be desired had been so carefully taken into consideration.

Mr. J. F. POWELL asked if any member had ever seen a panoramic picture that had been taken on more than one negative, invisibly joined in the printing, as he thought it would be quite possible to do so quite imperceptibly with the use of vignetting glasses.

The CHAIRMAN remarked that he had got the best results by using a very long plate and a wide-angle lens. Johnson's pantoscopic camera had done very good work of that description, some of which, executed by a friend of his, he (the Chairman) had seen. He had also seen some very strange effects caused by his friend standing in the picture, and then dodging the camera while revolving, and sitting again in a different part of the same picture.

Mr. DANIEL exhibited one of Moore's wooden baths lined with pure rubber. The bath was considered to be beautifully finished, and furnished with a very nice arrangement for making it watertight, the top moving up and down in a slot, and not separating from the bath, thus preventing its being mislaid or soiled with other solutions. The rubber is fitted in such a firm and complete manner that it is almost impossible for the slightest leakage or connection with the wood to take place. Mr. Daniel considered it the greatest improvement that had been made in baths.

Mr. POWELL said he had been told that those baths could not be relied on after three years' wear; he had had, however, no personal experience with them.

Mr. DANIEL said that the evidence of a firm of dealers was that two or three professional land-captists had been supplied with them, and although constantly doing a large quantity of work, had used them for a number of years, and were still doing so.

The HON. SECRETARY then announced that the May meeting would be the last indoor meeting of the session, and hoped to see a large number of members to hear Mr. Biggs's paper.

The meeting, after some informal conversation, broke up.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board of Management of this Association held their monthly meeting on April 2nd, at 160A, Aldersgate Street.

The minutes of the previous meeting were read and confirmed, and Messrs. Broadhead and Crosthwaite (of Leeds), and Hutton (of Cheltenham), were elected ordinary members of the Association.

The other business of the evening having been transacted, the meeting adjourned till May 7th.

PHOTOGRAPHIC SOCIETY OF FRANCE.

AT the meeting of the 7th February, M. PELIGOT, member of the Institute, president of the Society, in the chair, a communication was read from M. Lamy, on the influence of heat, cold, and moisture in carbon photography. The result of M. Lamy's observations is that at a temperature above $+12^{\circ}\text{C}$. the bichromated gelatine becomes gradually insoluble* without the action of light. This fact explains what was formerly supposed to be the action of light continuing in the dark. So long as the gelatine has not become completely insoluble, M. Lamy prefers to consider it as *hardened*, and the hardening process is more active the longer is the time that has elapsed since the sensitizing, and more rapid in proportion as the atmosphere is warmer and moister. It is also greater in proportion to the length of time between the exposure and the transfer, and between the latter and the development. For this reason paper that has been bichromated one day should be

* To a note M. Lamy thinks it necessary to remind his hearers that the gelatine becomes at once partially or totally insoluble when the room in which the tissue is hung up to dry after being sensitized is very small, and its temperature very high; it is only partial when the room is large, and the air is kept continually renewed by opening the door. It is therefore indispensable to bichromatise and dry the tissue in a room which is not artificially heated. When, during rainy weather or the prevalence of a thaw, the tissue refuses to dry, the best method of obtaining desiccation is to suspend it in a closet at the bottom of which is a large, closely-covered pan full of very hot water. The closet must have an aperture above and below to create a draught.

used the next, and it is necessary to transfer and develop as soon as possible after exposure. Paper, however, that has been sensitized some days ago, or that cannot be transferred and developed immediately, may be developed by using a warmer water, to the extent of 5° or 10° more for every day of delay, provided that the water be maintained at the same temperature during the whole operation; or the same effect may be produced by adding to the water a little liquid ammonia or solution of sodium carbonate. Care must be taken in each case that the water is not too hot or too alkaline, or the development will be too rapid, and cause white spots in the half-tones. But when the thermometer stands at a point below + 12° C. the hardening takes place more slowly, and the development is easier and more regular. On the other hand, the image is weaker in the same degree as the thermometer stands below + 12° C.; moreover, a tissue recently sensitized can be developed in a water as cool in proportion as the tissue itself has been submitted to a lower temperature during the exposure. The remedy for these defects consists, as M. Lamy points out, in prolonging the exposure, the indications for which he obtains by the use of his actinometer, described in our French Correspondence (see PHOTOGRAPHIC NEWS for December 27th, p. 614).

In a few well expressed and sympathizing terms M. DAVANNE alluded to the loss which photography in general and the Society in particular had sustained by the death of M. E. Lacan, the late editor of the *Moniteur de la Photographie*, and it was resolved to address a letter of condolence to the widow.

M. DAVANNE also placed at the disposal of the members a number of copies of a tract by M. E. Bazaine on the work, researches, and discoveries of M. Poitevin, and presented the first number of a new periodical, *Les Petites Affiches Photographiques*.

M. FABRE, of Toulouse, presented two works, one the *Aide-Memoire de Photographie* for 1879, and the other a tract entitled *Renseignements Photographiques*, on the employment of photography in scientific investigations.

Propos of the latter, M. PERROT DE CHAUMEUX drew the attention of the meeting to a work by M. Radau, recently published by M. Gauthier-Villars, on photography and its scientific applications, in which an interesting account is given of the services that photography is able to render to astronomical and microscopical observation.

A letter was read from M. LEON VIDAL, announcing the organization of a series of lectures on the Industrial Reproduction of Works of Art; and another from M. BRAUN, stating that with dry emulsion plates he had been able to obtain the same results as with wet collodion.

A communication was read from M. LAIR-DE-LA-MOTTE on the results that he had obtained by developing gelatino-bromide plates with the carbonates of ammonia and soda. He prefers, as a rule, the salt of an alkali whose composition can be readily determined, to the common liquid ammonia found in the shops, the strength of which is very variable. The following is the composition of the solutions of the two salts which he employs:—

A	{	Water	100 cub. cents.
		Ammonium carbonate	25 grammes
		Potassium bromide	1·2 "
A ₁	{	Water	100 cub. cents.
		Ammonium carbonate	25 grammes
or else—			
S	{	Water	100 cub. cents.
		Sodium carbonate	25 grammes
		Ammonium bromide	1 gramme
S ₁	{	Water	100 cub. cents.
		Sodium carbonate	25 grammes

These solutions when made with warm water are nearly saturated at this time of the year. The plate, having been washed for five or six minutes in water, is plunged into a dish containing (for a plate 18 by 24 cents.) 125 cub. cents. of a 1 per cent. solution of pyrogallic acid well mixed with from 12 to 15 cub. cents. of good beer, and kept then for nearly a minute. The plate is then withdrawn, 4 to 5 cub. cents. of the solution A, or else of the solution S, added to the bath, and the plate again immersed in it for thirty or forty seconds; no image will yet appear. Again 3 cub. cents. of A, and 2 of A₁ (or working with the soda solutions of S and S₁) are added, and the plate once more immersed for about half a minute; the image will now make its appearance. The development may be continued, if necessary, by adding more or less of A and A₁, or of S and S₁, as the case may

be. Using the sodinm solution for developing negatives of gelatino-bromide, whose colour is highly non-actinic, too great intensity may possibly be produced, for which, probably, a shorter exposure may be recommended as a remedy. With an alkaline development any required degree of intensity can be obtained; still, if it should be insufficient, the image may be intensified by a mixture of pyrogallic and acetic acids containing about ten per cent. of beer.

After the reading of extracts from the home and foreign journals by M. PERROT DE CHAUMEUX,

The financial statement of the Society for the year 1878 was presented by the Treasurer, and the officers for the ensuing year elected. M. PELIGOT, Member of the Institute, was again appointed President.

M. CHARDON communicated the result of his experiments with Russian cotton wool which had been introduced to the notice of the Society by M. Warnerke. The peculiarity of this wool appears to be that all the resinous constituents are removed by treatment with steam. It has been found useful in the Russian Medical Service, instead of lint, for dressing wounds. Its advantage for the preparation of pyroxyline appears to consist in its greater sponginess, owing to which it becomes immediately saturated with liquid. In ordinary cotton, the resinous substance which coats each fibre resists the direct action of the acids, so that they become more and more dilute, and their effect is considerably modified. Hence is produced a mixture of various kinds of pyroxyline having different degrees of solubility. On the other hand, it seems probable that ordinary cellulose is not a homogeneous body, but that each body contains substances which are acted on successively, resulting in a complex compound. By precipitating the pyroxyline from normal collodion by means of water, and collecting and redissolving the precipitate, M. Chardon succeeded in obtaining an excellent collodion for emulsion purposes. As regards the particular cotton in question, his experiments proved that the penetration of the acids was more rapid, and the resulting pyroxyline more homogeneous, than with ordinary cotton. He prepared it by immersing the cotton in a mixture of potassium nitrate and sulphuric acid for five minutes at a temperature of 80° C. After resting for some days, the collodion was sensitized by a solution of 12·25 grammes of silver nitrate in 120 cub. cents. of alcohol; it acquired that orange-red colour which is regarded as a proof of its good quality. The excess of silver was then neutralised by 10 cub. cents. of collodion chloride of cobalt, and precipitating with hot water removed a larger proportion of the soluble products, mixed with particles of silver bromide, which were no longer retained. Finally, the emulsion was prepared by the following formula:—

Alcohol	40 cub. cents.
Quinine	0·2 grammes
Dried emulsion	6 "
Ether	60 cub. cents.

The general result obtained by M. Chardon is, that the sensitiveness of an emulsion made with the Russian cotton is about the same as that made with his own doubly precipitated cotton, above described; but in the fixing he observed that the image obtained with the former is softer, and its effect more uniform. Further experiments are, however, he thinks, necessary before arriving at a decided opinion.

M. FERRIER submitted some of his pictures obtained with the gelatine emulsion process, and gave a detailed account of his method of working.

M. STEBBING mentioned that, according to his experience, the gelatino-bromide process is equally, if not more, rapid than that with wet collodion. He uses iron oxalate as developer.

M. CALOIR sent for exhibition at the meeting several samples of a new substance that can be used in retouching negatives. This product has a certain similarity to that which, under the name of *chaoma*, M. Carotte exhibited to the Society in 1877, and recommended for the same purpose. It rejoices in the sufficiently complicated name of *Nach-Sel-Fujube d'Ile-Mea*, and is sold in the form of lozenges, each one of which gives a litre of solution. This solution is flowed like gum over the surface of the negative, which must have been well drained, but be still moist. If the negative has been dried, it must again be moistened before being coated with this species of varnish. The film can readily be worked on with either the pencil or the point.

M. BARDY gave an experimental demonstration of the means of recognizing with rapidity and facility the impurities of commercial glacial acetic acid. It is hoped that M. Bardy will on a future occasion publish his communication on this subject.

Talk in the Studio.

MR. J. TRAILL TAYLOR.—*Anthony's Bulletin* announces to its readers that this gentleman has kindly consented to furnish articles for its columns, which will thus present additional originality and interest.

RIVAL PROFESSIONAL BEAUTIES.—*Professional Beauty* (with photograph of Zulu): "Isn't it too bad? After we have lavished our loveliness on an ungrateful public in every pose in which skin-tight costumes could show it off, they are actually allowing these wretched black creatures to appear in—no costume at all."—*Funny Folks*. The same paper, in a skit on the budget, suggests a penny stamp duty on cartes-de-visite—those of criminals and professional beauties to bear a sixpenny ditto.

AMERICAN v. ENGLISH MECHANICS.—Mr. W. J. Stillman, writing in the *Scientific American* on the mechanical genius of American workmen, complains of the want of ingenuity and skill of English workmen. He says:—"I am myself sometimes attacked by a mechanical idea, and now and then it results in an invention. It happened on one occasion the product was a photographic camera-obscura, which involved some mechanical principles new to this kind of work. I made an elaborate working drawing full size, with details of all new parts in separate drawing, and sent them to a camera maker who had the highest repute in London, but after some months they came back with a message that the arrangement was not practicable. I then went personally with the drawings to another workman, who was really the most ingenious in this branch I ever found in England, and even with him was obliged to make a wooden working model of the whole thing before I could make him see that it would work, and I had to watch the construction from beginning to end, intervening at every new step to keep it what I had planned." Notwithstanding this, the best photographic apparatus in the world is undoubtedly made in England. But the English workman, or, more correctly, the metropolitan workman, dislikes to make a single article to a special pattern. It is best to go to a provincial mechanic for such work. Mr. Stillman adds, we think unfairly:—"The English workman in general is insensible to those nice degrees of excellence, neatness, and precision in the manipulation which the American workman catches so readily."

A POWERFUL SPECTROSCOPE.—In the young science of spectroscopy, as in others, an important element of progress is the improvement of instruments for dealing with the phenomena presented, and many minds are engaged on this. A new spectroscop of remarkable power has been brought to the notice of the French Academy by M. Thollon. Its chief feature is the use of sulphide of carbon prisms, which are closed laterally, not by plates with parallel faces, but by prisms of the form of Amici's—i.e., having curved sides meeting at an angle (which, however, is much smaller than Amici's prism). The refringent angles of these prisms are in an opposite direction to that of the sulphide prism. Two of these compound prisms are substituted by M. Thollon for the simple prisms in a spectroscop, which he formerly described to the Academy. Without going into further details, we may simply state that an enormous dispersion is obtained; with a magnifying power of 15 to 20 times, the spectrum has a length of 15 metres. The angular distance of the D lines of sodium is about 12', whereas that produced by M. Cassiot was only 3' 6". This instrument should throw considerable light on the structure of the spectrum, and M. Thollon has already noticed some interesting facts. The lines of sodium and magnesium present a dark nucleus passing into a nebulosity, which becomes gradually merged in the continuous spectrum. Many lines have been split up, and all that have been thus resolved have been found to belong to two different substances. One of the hydrogen lines presents a nebulosity without a nucleus. M. Thollon remarks on the magnificence of the spectrum of carbon from the electric arc, observed with the new instrument. The spectra of iron, copper, and magnesium in the same arc were also seen with admirable clearness and brilliancy. These new spectroscopes have been constructed for M. Thollon by the able optician M. Laurent.

CELLOIDIN, A SUBSTITUTE FOR GUN-COTTON.—A new kind of nitro-cellulose has lately been placed on the market by the chemical works of E. Schering, in Berlin. This has been named *celloidin*, and appears to be a very useful substance, both for the photographer and for the pharmacist. It is put up in plates which are neither explosive, like gun-cotton, nor

readily inflammable. Ignited it burns like paper, and when heated in a test-tube, it chars slowly. Its transport by rail, waggon, or mail, is therefore unattended with danger. This substance is soluble in alcohol and ether in any proportions, and yields a perfectly clear solution, leaving no residue. Each plate weighs about 2.0 grams (seven ounces) and represents, when completely dry, exactly 40 grams of pure celloidin.—*Schweiz. Wochensch. f. Ph.*

To Correspondents.

ELECTRIC.—The defect in the cards enclosed is due, we think, to the mounting material used. It may have contained some injurious substance, or it may have become sour. Our first impression was that such a cause was in operation, and on soaking the card in warm water to remove the print from the mount, we found an accumulation of the mounting material laid thick just at the point where the patch of spots was present.

G. B.—The best remedy for the pinholes and comets in your negative is the addition of a little bromide to your collodion. The experiment you have been making in preparing your own collodion, and using iodides only, was common in the early days of the collodion process, is a very interesting one; but you may take it for granted that the change, now universal in practice, is based on experience. Good results were, undoubtedly, at times obtained with simply iodized collodion; but the conditions were very precise, and, if not carefully observed, many troubles were encountered. The collodion deteriorated in sensitiveness steadily after it was iodized; but if used too soon after it was iodized, streaks, spots, comets, and fog were encountered. Besides rendering the collodion more sensitive and making it keep better, the removal of comets, and such abominations, alone made the use of bromides a great boon.

F. R.—Your toning bath is spoiled beyond remedy. You must make a fresh one. The brown discoloration you describe is due to contact with hypo. Throw down the gold with iron, and so save it for making fresh chloride of gold. 2. We shall make the announcement in due time.

J. JUN.—The addition of citric acid to a silver bath will throw down citrate of silver if the solution be neutral or alkaline, but not if free nitric acid be present. The experience of the gentleman in question is, that all samples of nitrate of silver in commerce at the present time are neutral. The precipitate of citrate of silver weakens the solution very much, as citric acid being a tri-basic salt, three atoms of silver are precipitated by each atom of citric acid.

G. F. M.—The difficulty caused by the tendency in magnesium ribbon to go out, so causing intermission of light, may be overcome by keeping a gas flame or a spirit light burning underneath it. The primary difficulty in using this light for portraiture is the dense white smoke which accumulates. A method of getting rid of this was once devised, but never published.

M. M.—We have often explained that the difficulty in obtaining a rich deep tone in prints was due rather to the negative than to the quality of the paper or to the toning bath. With a thin weak negative, wanting in contrasts, no really rich print can be produced. The shadows should be nearly transparent, and the high lights dense. With a thin poor negative a rich black tone cannot be obtained, because a sufficient depth of printing cannot be secured in the shadows without losing the purity of the whites. When sufficiently printed to do justice to the lights, the prints will tone to a brown, or if carried further to a slatey grey, but not to a black.

G. B.—The notion of producing stereoscopic relief in a single figure, by projecting the images from two lenses one upon the other, has often been entertained, but is the result of a misconception; it cannot be done. By skilful drawing and management of light and shade, an effect of great solidity in a single image may be secured, as is often done in scene painting, and occasionally we have seen a similar effect in photographs. But the attempt in question is a waste of time.

PORCELAIN.—In the communication to which you refer, the writer assumes that the reader knows how to produce transparencies, and merely gives his method of treating them to imitate porcelain. They are evidently printed by contact with the negative by the aid of a gas light. A two-grain solution of pyro, with thirty minims of acetic acid to the ounce, will answer. 2. Enlargements can be produced on collodion by treating a darkened room as a camera. 3. Technically, porcelain and opal glass are not the same, but in common phraseology they are often treated as the same, and generally mean the same thing in relation to photographs. If you have a solar camera you can enlarge on sensitive albumenized paper when you can command sunlight; but it is a troublesome process. With a powerful condenser an hour of bright sunshine might serve. It is difficult to develop albumenized prints. A saturated solution of gallic acid is used for developing paper prints. Several correspondents in our next.

The Photographic News, April 18, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. THE OWNERSHIP OF THE NEGATIVE AT HOME AND ABROAD— HELIOSTAT OR HELIOGRAPH.

The Ownership of the Negative at Home and Abroad.—The ownership of the negative appears to be receiving attention once more abroad. It is a matter of much importance to the photographer, and one, therefore, that ought to be definitely settled. In this country no doubt the new Copyright Bill will contain a clause upon the subject, although it has been for years past an accepted dictum that the photographic negative belongs under ordinary circumstances to the man who produced it. Of course there are times when the photographer can make no claim, as, for instance, when his assistance has been invoked for the avowed purpose of securing the negative, or when he may be desired to do work with another man's apparatus. Again, it sometimes happens that a photograph is secured under the joint superintendence of two persons, in which case a dispute of claim may well arise. We remember some ten years ago an instance of this kind that was brought before the Paris law courts. The matter in hand referred to a negative of no less a person than the late Emperor of the French, who was presented upon horseback, a pose of which no other good picture was in existence, so that the proprietorship of the negative was an important affair. The negative was the work of that eminent firm MM. Bisson frères, and of its intrinsic value there could be no question. MM. Bisson frères had been commissioned by a French painter, M. Yoon, to take a portrait of the Emperor, and MM. Bisson frères contended that when they had supplied copies of such portrait, then the commission had been duly executed. But M. Yoon claimed both negative and copies. At first sight, no doubt, the photographer appeared in the right, but the circumstances under which the photograph was taken materially altered matters. M. Yoon swore distinctly that he had simply engaged the photographer to act implicitly under the former's directions. M. Yoon desired to paint a portrait of the Emperor on horseback, to be the centre of a battle picture representing the fight at Solferino, and, being unwilling to trouble the august sitter for a lengthened sitting, he had constructed a model horse upon which to pose the Emperor. M. Yoon further stated that, besides posing his sitter, he managed the lighting, and decided upon the point where the camera was to be placed, thus fulfilling all the artist's work in connection with the taking of the photograph; the photographer's labours were confined, he averred, to the purely technical portion of the work. The Court in the end adopted M. Yoon's statement, and, under the circumstances, naturally enough declared the negative to be the property of the artist who had commissioned the taking of it. That it was the joint production of two men, an artist and a manipulator, the Court said was evident; and as one man was avowedly working under the direction of the other, the property must be given to the employer, and not the employed. Few would be disposed to cavil at such a verdict; but as the case is one that is sometimes cited to prove the photographer's right to the negative is not an incontrovertible one, the circumstances under which the case was given against the photographer should be remembered. In this country, he who desires a negative, as well as print therefrom, has no difficulty in obtaining it, provided he makes known his wish *before* the work is executed. Photographers do not desire such work on commission, as a rule, as it is foreign to their mode of business; but anyone desiring to possess a negative photograph would have little difficulty in securing what he wants. But he must be prepared to pay, for not only does a negative mean actual value of material, but forms part of the photographer's stock-in-trade. Moreover, the anxiety of some people to possess negatives is very foolish on their part. If they consider a negative valuable and worth

keeping, it is far safer in the hands of a photographer than their own. Besides the ordinary risk to which glass is liable, the photographic film is subject to dangers of its own, and these the photographer knows how to guard against better than his patrons.

Heliostat or Heliograph.—The heliostat apparatus which is now employed, as already mentioned, for sunshine signalling, both in Afghanistan and Zululand, has received the name of heliograph by Mr. Mance, who has initiated the method of working. As we have stated already in these columns, the plan of signalling is simply to reflect an image of the sun to a distant station. As the sun is continually moving—or, rather, the earth—the angle at which the mirror must be to do this requires to be changed also, and hence the heliostat with its clockwork arrangement is made use of. The heliostat mirror follows the sun, and the consequence is that, after it has been once properly adjusted, a bright flare—the reflected image of the sun—is seen at the distant station. This flare or spot may be observed by mechanical means at any time, and the appearance and extinction of the light constitute the signals. The light shown for a brief period is called a dot, and for a longer period (three times as long) a dash. All the letters of the alphabet are made up of dots and dashes. The letter E—that most used—is represented by a single dot or short flash; the letter T by a dash. A is shown by a dot followed by a dash; N by a dash followed by a dot, and so on. But although Mr. Mance calls his modified apparatus a helio-graph, it does not write down the signals. It is a pity, by the way, he has chosen the name which has been made use of by photographers for years past. Helio-graph and heliogravure, signifying an impression by the sun, just as photograph signifies an impression by light, are the earliest terms employed by Niépce and his colleagues, and yet Mr. Mance has applied the term again to his light-signalling apparatus, which, unlike the telegraph and other "graphs," does not write or impress at all. Since, however, the employment of Mr. Mance's apparatus has now come into general operation in the field, perhaps it would be well if it could be converted into a true heliographic instrument, and write down its signals. There should be little difficulty in bringing this about. As we have said, the station to which the signals are sent observes a bright flare or spot, sometimes for a short period, sometimes for a longer one, or, in other words, sometimes for a duration of a second, and sometimes for three seconds. The light is very intense, for it is a reflection of the sun itself, and there can be little doubt that if it struck a sensitive film, it would at once impress the latter. This sensitive film might be iodide paper, to be developed hereafter with gallic acid, or, in fact, any similar substance. The bright flare would be caught up by a condenser and thrown upon the sensitive sheet in the form of a tiny spot. The tiny spot would at once impress the sensitive sheet, and if the sheet were made to travel along by clock-work at a certain fixed rate, then the tiny spot would make a line upon the film. If the bright spot was visible for a second only, the line made upon the moving sensitive film would be a very short one, while in the case of its shining for three seconds we should have a line of appreciable length. In fact, we should have a dot or a dash upon the sensitive film according as a short or long signal was flashed. In this way a truly "heliographic" apparatus would be at hand, and we think it would be worth Mr. Mance's while to consider whether such an improvement could not be made.

FRENCH CORRESPONDENCE.

M. ARTIGUE'S PHOTO-TRACING PAPER—AUTOGRAFIE POLYCHROME—DEATH OF M. BACARD, SEN.—PHOTOGRAPHIC SOCIETY OF FRANCE—SOCIÉTÉ DES ARCHIVES—GENERAL NEWS
Artigue's Photo-tracing Paper.—When a specialist meets with some novelty that interests him, he is absolutely

like a child who wants to break his toys to see what is inside, but whose curiosity is never satisfied. For this reason I had a great desire to find out all about the *Papier-Artigue*, so I betook myself to the inventor himself, and begged him to show me all the details of his invention. Having seen the whole process, which he was kind enough to exhibit to me, I am enabled to give a fuller account of the *Photo-Decalque*, as M. Artigue has named it, than I could do in my correspondence published in your issue of the 4th of April. In every other process with tracing-paper the draughtsman is compelled to make a vigorous drawing in thick India ink; he has also to be careful in securing the success of the photographic operations. By this new method he has only to transfer his tracing to the special carbon paper prepared by M. Artigue, and in less than ten minutes he will obtain a beautifully distinct negative copy *without the aid of daylight*; he has not even occasion to use the printing-frame. The carbon paper, which is coated at the back with a film of potassium bichromate, is merely thrown into water; the film then separates, and the drawing appears as a white line on a black ground. On exposing this negative in contact with the copying paper for three minutes in the sun, or for from ten to twelve minutes in the shade, a positive print is obtained. This print gives the lines of the drawing in black on a white ground, absolutely the same as if it were the original itself. The great and peculiar advantages of this process are, that it is particularly simple, and that it is not necessary, as with other carbon papers, to use hot water and its concomitants; the inconvenience of two sheets placed side by side is also avoided. It will be seen at once that the progress realized is a very remarkable one, and we may be permitted to express a hope that M. Artigue, who is a photographer of great ability, will succeed in adapting the process to carbon photography in general. The nicety required in the various operations of this branch of photography, and the attending difficulties, are the causes of the carbon processes being relinquished—for that they are being relinquished every day affords a fresh proof—except for transparent photographs and enlargements. In these two processes carbon still maintains its sovereignty, but in all others it is rapidly losing its power. It would not be wonderful if M. Artigue, who already possesses a key to the secret, were to restore the carbon monarchy, though without offending the republican convictions which are now so prevalent in France. M. Artigue has discovered another very ingenious method of producing a negative. A piece of tracing paper is written or drawn on with a pen dipped in a specially prepared ink, and a brush moistened with a certain mixture is passed over it, when the tracing becomes transparent. So great is the transparency of this negative that any number of excellent prints in black line on white ground may be taken from it in a very short time. In this respect it possesses a manifest advantage over transfer papers in which the line is coloured. The first-named process of M. Artigue is more especially valuable on account of its producing good negatives. For this reason it has been adopted in the office of the General Staff of the Army for the reproduction of military charts, as well as the Department of the Minister of the Interior for copying survey maps, and in both cases it is preferred to other processes, notwithstanding its costliness.

*The Autographie-Polychrome Process.**—As I am on the subject of new reproduction processes, it would not be right for me to omit to mention one which has received the name of *autographie-polychrome*; it is worthy of notice, no less for its very great simplicity, than for the rapidity with which it can be worked. By employing this process, also, a great saving is effected both of time and money,

* It will be noticed that in my letter which appeared in your issue of 4th of April I erroneously applied the name of *polychrome-autographie* to a process depending on the use of a substance consisting mainly of an aniline base. This is an error which my readers will probably have detected themselves, as I went on to speak of the prints being only blue and violet.

as the long and costly labour of making copies of drawings or plans in one or several colours is entirely avoided; all the colours of the drawings, whether worked by the pen or the brush, are reproduced at the same time by a single printing operation. This new system, the solution of a problem that has been long sought after, will be found to be indispensable in many branches of art manufactures. By means of it it is possible to obtain from twenty to forty copies of a drawing of any size; neither press nor laboratory is required, but merely the special colours and paper of the inventor. It appears to me that some account of useful inventions of this kind will be of interest to your readers, especially as without publicity being given to them, and attention being drawn to their merits, they run the risk of being ignored altogether. Whenever, therefore, I meet with a new process possessed of any value, and connected in any way with photography or its applications, I intend to describe it in my correspondence. It is very possible that similar methods are being worked in England; but in making known those which are introduced in France, I am giving an opportunity for comparison, which may lead to improvements on one side or the other. Giving this kind of information will have the additional advantage of calling attention to infringements of patents and copyrights, where such exist.

Death of M. Bacard the Elder.—In the course of the last few days we have had to deplore a sad loss in our profession. M. Bacard, senior, has at last succumbed to a painful disorder under which he had been for a long time a sufferer. The deceased gentleman was an artist of great experience, whose photographs were very highly valued. He was the proprietor of a large and prosperous establishment, and in the course of a hardworking and industrious career he has turned out many skilful and well-known pupils; among these his son, M. Bacard junior, who has a separate establishment of his own, is one of the first photographers of Paris. The death of M. Bacard causes a notable blank in the list of portrait photographers, and the news of it will be received with universal regret by the profession, who lose a respected colleague, and by the public, who will miss a favourite artist.

Photographic Society of France.—The general meeting of this Society, which was held on Friday, the 4th of April last, lost some of its anticipated interest in consequence of the adjournment of two subjects which had been announced for discussion: I refer to the promised communication of M. Ch. Cros, on "Improvements in negatives by an optional displacement of the actinic action," and to the expected exhibition by Mr. Gurney, of New York, of some specimens of photographs "coloured by his new process." These two important questions were, however, referred for consideration at the next meeting. Let us hope that "*Ce qui est differe ne sera pas perdu*," otherwise the Photographic Society will be giving the lie to an old proverb. We had, however, the pleasure of hearing at this meeting some observations from M. Stebbing, some remarks on the development of gelatine bromide, and of examining a large number of photographs exhibited by various members as specimens of their skill or illustrations of their researches. But the great attraction of the meeting was a special question of photographic chemistry treated by M. Bary with his usual talent: "The use of various solvents of pyroxyline in the preparation of emulsions." M. Bary also exhibited to the Society a novel instrument, which he calls the "chromographe," for obtaining, without the use of a lithographic stone or inking roller, a large number of copies of the same drawing. This instrument I have already brought to the notice of the readers of the PHOTOGRAPHIC NEWS in my correspondence which appeared in your issue of the 4th of April last. At the same meeting M. Davanne read a report on the "Causes of Halos," by the Committee on Emulsions.

Societe Francaise des Archives Photographiques, Historiques, et Monumentales.—As I announced in my letter which

appeared in the PHOTOGRAPHIC NEWS of the 14th March last, this Society held its first scientific excursion on Sunday, the 6th April last. The wet weather of that day did not succeed in damping the ardour of the excursionists who had assembled at the Limours station; in spite of the rain they steadily worked through the programme of their expedition. Several photographs were taken by M. Letellier, the indefatigable director of the society, of the ruins of the feudal chateau of Chevreuse, as well as of views on the estate of the Dukes de Luynes at Dampierre. Let us wish the Society more favourable weather for their next excursion, which is fixed for the 20th of this month. On that occasion M. Guilleminot has promised to subject to trial the new travelling apparatus for photographers of his own designing, and several archaeologists will explain and describe the historical buildings which are to be the object of the expedition.

Miscellaneous News.—The lecture given by M. Pierre Petit, junior, on photography and its various applications, drew a very numerous audience, a fact which goes to prove that everything relating to our art-science has a charm for those desirous of knowledge, and meets with a favour that steadily increases on each successive occasion.

The definitive transfer of the valuable photographic business of M. Walery is the great news of the day, perhaps because the *denouement* was so very unexpected. In the French Correspondence of the PHOTOGRAPHIC NEWS of the 22nd November last, the late Ernest Lacan informed your readers that M. Schemboche, of Florence, had entered into an arrangement with M. Walery to succeed him in his business. Now we learn that M. Schemboche will take over the establishment of M. Dupont, in the Avenue des Champs Elysees, while M. Dupont becomes the successor of M. Walery. This turns out to be the final result of a convention concerning which we have heard many contradictory surmises, but the question still remains whether the strife will cease from want of combatants. MM. Dupont and Schemboche will have to exhibit more ingenuity and activity than ever to establish a real competition against each other, after having concluded an amicable arrangement whose motive is not understood by the public. At the same time, it must be acknowledged that with private interests the public have no right to be concerned.

K. VERSNAEYEN.

ON THE SELECTION OF SUBJECTS FROM NATURE SUITED FOR PHOTOGRAPHY.

BY DR. ALEXANDER HUNTER.*

In the following paper prepared for this Society with some care, and after thirty-two years of photographic and artistic labours in India, I propose to discuss the subject of landscape art under the heads of *pastoral*, *agricultural*, and *industrial*, trusting that the photographs which I may be able to hand round and to lay on the table may serve to illustrate more forcibly what I wish to express, than anything I could say in mere words.

Landscape art opens up to the photographer, perhaps, a wider field than any other branch, yet I believe it is more difficult to attain to anything like eminence in pure landscape than in architectural or portrait photography, for the simple reason that it calls for a more thorough acquaintance with the principles of light, shade, composition, and general breadth of effect, than most of the other branches of photography. In fact, a real artist can show off his talent better in landscape photography than in any other department.

I dare say I may be treading on very tender ground by making such a broad assertion, but I do so after twenty-nine years' practical experience of photography in all its branches, and since the art was almost in its infancy. Now it has attained to what we, in our self-sufficient wisdom, are

inclined to look upon with complacency, as being pretty fair and honest progress towards perfection. I have no doubt that ten years hence, if any of us are spared to look back upon the labours of 1879, we will be surprised to think how easily we were pleased with what we were producing. There is one delightful encouragement that we all must have in our photographic labours, and this is a point that we should not be ashamed to acknowledge—at least three-fourths of our labour for which we take the credit is God's own work: we are fellow-labourers, but can do little more than prepare the paper, the chemicals, the apparatus, and other appliances. Let us be thankful that we have made the progress that photography can now show, but let us not be proud, conceited, or boastful, or we may have little future progress to talk of at these or other meetings.

But to proceed with more practical details. In the selection of subjects for pastoral photography, there are a few simple rules to guide us, that must be attended to if we would wish to produce a pleasing picture, and some of these are the same as those that would guide an artist in painting landscapes. The following are of primary importance:—

1. Whatever may be the subject selected, take care that the principal object does not come *bang* in the centre of the glass, or it may remind you of "here stands a post."
2. Get it a little to one side, with a smaller object on the other to balance or support it.
3. Don't get the horizon in the centre of the glass, with half for the sky and half for the picture, as this creates a difficulty with the details in the foreground, and throws a considerable portion of the nearest part of the picture out of focus, while it leaves the middle distance, which is often the most telling and important part of the view, out of its proper and relative position.
4. As a general rule, the best position of the horizon is one-third from the bottom of a picture, leaving two-thirds for the sky, hills, distance, &c. Bonnington, Collins, Creswick, and Sir Augustus Calcott, with many of the best artists of the Flemish School, have now and then kept the horizon one-fourth from the bottom, and this gives greater importance to the figures or animals which are in the foreground. If it is desired to represent views or scenery from a height, this rule may be reversed, and the horizon may be one-third from the top, leaving two-thirds for the foreground and near details. There is this danger, however, with the latter mode of treatment, that if figures or animals are to be introduced, they don't come properly into the picture, and either look dumpy, distorted, or as if they had been sat upon or were lying on their sides; and objects, animals, or figures from this standpoint should not be attempted in photography, as they will have an insignificance, and will sometimes appear as if tumbling out of the picture. To put this more pithily, you cannot take a good photograph, picture, or sketch of a man, from a position where you see the circular form of the top of his hat. Turner used to have a very laconic way of putting this: "Your own knees or your own toes will never make a good object in the foreground of a picture."
5. It is better to point the camera away from the sun, or slightly across the path of its rays, than directly facing it.
6. In bright sunny weather, the best views, I believe, are generally obtained in the mornings after the dew has risen, or before it begins to fall in the evenings. In India, we used to go out about 5 a.m., so as to be ready to work from 7 to 10, then home for breakfast and a bath, and perhaps a little time to read or to rest, luncheon at 1, and out again from 2 till 6 p.m., on rare occasions till 7 p.m. I have seen some good photographs taken when it was almost dark, but of course the exposure was then much longer. I have also seen good views taken in misty weather, and not a few during showers of rain; on the whole, I prefer a showery day with large white clouds, to a hot steamy day or a dull murky one. I have never worked at photography with snow on the ground, but I should think that with a moderately clear sky the quality of light would be good, though the position of the bright light is reversed by the snowy landscape, and the sky is often of a leaden grey. I have no experience of

* Extracted from a paper read before the Edinburgh Photographic Society.

work under a black Glasgow or Greenock fog, a London yellow peasoup-like fog, an Edinburgh murky fog, a grey, leaden Hampshire fog, a green Leith and Portobello chemical fog, a pure white Thames steamy fog, or a Haddington eastern haur, but this I know; that two, if not three, of these are prejudicial to health, and presumably to photography also.

We come now to the division of subjects into different classes. Pastoral landscapes are usually associated with flat, alluvial, or nearly level country, coast scenery, or views on rivers, such as we see in the pictures of Cuypp, Paul Potter, Bonnington, and a number of our modern artists. The difference, however, between photographs and pictures of this class is, that the artist has the power of introducing shadows and of concentrating the effects near the horizon, and of placing the figures, animals, or objects in such positions as will please the eye and assist the composition or general effect. All that the photographer can do is to alter his own position, or that of his camera, to try to get everything into the best possible position; but in doing this, an awkward branch, too large a stone, or an unfortunate blaze of light, or a hard cutting shadow, will sometimes spoil what would otherwise be a fine subject. As a general rule, for subjects of this class, it is well to select a clear open space immediately in front of the camera, and this avoids a difficulty. A windy day is often the source of a great distress to the photographer, by blowing about the trees, grass, or plants in the picture. Those in the foreground usually suffer most, as they seem to be shaken the most violently. It has been frequently objected to photography that it gives too clear, sharp, and cutting an outline, but this may sometimes be obviated by not focusing too sharply. I have occasionally seen artistic sketchy-like photographs produced where none of the picture was truly focused, but there is always a risk of producing a muddled effect.

By combination printing the artistic photographer can generally produce pictures alike pleasing and satisfactory in their results. If, however, the different parts are not artistically and skilfully combined, they can neither be pleasing nor truthful.

Agricultural subjects differ from pastoral generally in being more confined, and of a local character; in these there are points of peculiar interest that require to be seen closer at hand, and to be more clearly defined. Thus, for instance, views of coffee and tea plantations, and scenes on farms, with cattle, agricultural and other implements, require to occupy prominent positions. Skies are not required in such subjects, or a very little bit in an upper corner of the scene is often sufficient.

We had some interesting discussions at the last meeting of this Society on the subject of magnesium and other artificial lights. I did not think that that important subject received the attention it deserved, for some of the photographs were nearly as good as any of the portraits that have been taken by the light of the sun; they had a Rembrandtish effect, and remarkable definition. There is no doubt that the sun's rays give us the best light, but the quality of that light is very variable in different countries and at different seasons of the year. In the hilly parts of India, as of most other countries, it is usually better than in the plains.

The photographer has often more light than he wishes, especially in hot climates or during the middle of the day; under such conditions, the pictures are apt to come out too black and white, and to obviate this, dull rainy days are preferable, or working in the mornings or evenings, as I have already hinted.

I must now conclude by informing you that photography (as well as the fine arts) is making very rapid strides in India: many of the rajahs and wealthy natives practise photography with success, and keep assistant photographers in their pay; and I assisted in the establishment of thirty-three schools of Industrial Art in India, and one at Jaffa in Ceylon. Most of these are in a prosperous state, and are well attended and liberally supported by all classes of the

community. We commenced in Madras in 1850, and had within four months six hundred pupils, each paying one rupee or two shillings a month for instruction. I had eight teachers—European, East Indian, and Native—to assist me, and in twenty-three years we were able to provide situations for 2,020 young men. The work was begun as an experiment, not as a remunerative speculation; it greatly prospered, and now it goes on steadily and unostentatiously, without giving me any further trouble or anxiety.

Photography I found to be a great aid to art, and it surprised, astonished, amused, or excited the natives of India, but it did not rivet their attention so forcibly as the arts of modelling, carving, and sculpture, for these they understood and had practised successfully for many centuries, though often in a grotesque, rude and quaint, and sometimes in a questionable way in the decoration of their pagodas. Though India can boast of possessing some of the finest marble and bronze statues and busts in the world, the work of British artists, she cannot be said to possess much in the way of fine, pure, and elevating art. Yet she possesses, perhaps, the largest and most beautiful quarries of marble, alabaster, and magnesian limestones of every shade and colour at Aymere, Jeypore, Jubbulpore (this is the finest quarry of pure white marble, 2 miles in length, and 120 to 160 feet thick, yet the only use made of it is for mile-stones). There are other fine quarries in Madras, Burmah, and Pogn. Besides these, there are extensive quarries of serpentine, cidote granite, white granites, black marbles, &c., in the Madras Presidency, all lying comparatively idle.

We are doing a great deal to educate the natives of India, and they are grateful for it; but could we not turn some of these neglected resources to account, and then do the same for Cyprus, for Africa, and for Russia, which seem to be in need of peaceful occupations?

PHOTOGRAPHY CAN AID ART, AS ART AIDS INDUSTRY.

Come, sister dear, and lend thy willing aid
To catch those passing charms of light and shade
That flit about as if in lively play,
And while we gaze, so quickly pass away.
Just watch that little brilliant sparkling light
Dancing about as if in free delight,
Like sportive lamb, from rocky bank or glade,
Skipping o'er leafy bough, then lost in shade.
The brush or pencil in the artist's hand
Can teach us to perceive and understand
That glorious book which Nature spreads to view.
But, yet, 'tis granted only to a few
To read and represent God's work aright,
Thereby to elevate, improve, instruct, delight.

EFFECT OF PROLONGED EMULSIFICATION IN THE GELATINE-BROMIDE PROCESS.

BY CAPT. ABNEY, R.E., F.R.S.*

I HAVE ventured once more to say a word in the discussion on the gelatine emulsion, as perhaps some experiments I have made may throw a light on the subject of the greater sensitiveness of this process after long emulsification. I would first call your attention to a statement I made some time last year in one of my papers, that silver bromide is incapable of existing in close contact with freshly reduced metallic silver, and I shall take this for my text on which to found my argument. If we take collodion, and highly bromize it with (say) ten grains of zinc bromide to the ounce, and try and use this in a bath, we shall find that the silver bromide will be formed rapidly, but that it lies entirely on the surface of the film, so much so, indeed, that it can be wiped off with a tuft of cotton wool and leave the transparent film of collodion behind. If we take plates so prepared, and, after exciting in the silver bath and washing thoroughly,

* Read before the Photographic Society of Great Britain.

transfer them to a bath of potassium bromide, we shall find that we have increased density of deposit, a transparent film becoming nearly opaque. When these plates are washed and dried, let them be exposed beneath a negative in the printing frame and be developed. If one plate be developed by ferric oxalate, we shall find that we get an image developed at first, but that on continuing the development to attain density we shall get either a perfectly black film, or an image so dark as to be perfectly useless, large granules of metallic silver taking the place of a fine deposit. Let the other plate be developed with pyrogallic acid and acidified silver nitrate, the image will be found to develop of the proper density and of the most delicate character. Let us try and reason out the cause of this difference. In both plates the silver bromide is in almost a continuous layer; but in the one the bromide, acted upon by light, is reduced to a metallic state, and that forms sub-bromide with the next particle of unaltered bromide, and so on, till the action is stopped by a want of continuity in the bromide. In the other, metallic silver is only deposited in the sub-bromide, and there is no tendency for the image to spread; the discontinuity or continuity does not affect the result.

Take another plate similarly prepared, but not dried, and flow over it a weak solution of gelatine; dry it, and again develop by the alkaline method. It will be found that the development takes place regularly and evenly, and that a very fine result is obtained, though still rather coarse. Why is this? The gelatine impregnates the bromide, and on drying there is a distinct separation of the particles. Now we may proceed to consider the effect of the long emulsification of the silver bromide in gelatine. At every instant the particles tend to separate into a finer and finer state of division, and the gelatine separates them individually, till, after a lengthened emulsification, the particles are excessively minute, and completely enveloped by gelatine. On coating a plate with such gelatine emulsion, and after drying, no two individual particles are in contact (recollect, I do not say molecules, as there probably are thousands of such in the smallest particle); and if any particle has been acted upon by light, that colour will be reduced to the metallic state. The use of soluble bromide seems to be in forming a compound with the silver bromide, which prevents its reduction; in other words, metallic silver in presence of this double bromide does not have the same effect as it has on the bromide of silver alone; hence when these individual particles are thoroughly separated, there is no need of the restraining action of the soluble bromide. Each particle has an individuality of its own, and is independent of the contiguous particles, and has no effect upon them. Now collodion is essentially granular; that is to say, it is not a continuous layer, whereas gelatine is; hence in the one case the restraining bromide is required, and in the other, where the emulsification has been long continued, it is not necessary. With washed collodion emulsion, where the amount of pyroxyline has been diminished, the tendency to fog is greater than is ordinarily the case; but when a preservative such as albumen is used, it takes the place of the pyroxyline. In many cases the substitute is the better of the two. Thus in albumen-her plates prepared with the bath, no restraining bromide was required to bring out an unveiled image, and an immense proportion of ammonia could be used; and again, the addition of gelatine to the developer in some shape or another often renders soluble bromide unnecessary; for the same reason, the particles of metallic silver reduced from the sub-bromide being prevented from transmitting to the neighbouring particle of unaltered silver bromide by the viscosity of the gelatine. Regarding the increased sensitiveness caused by prolonged emulsification, the separation of the particles into a minute size favours this, since there is more surface on which the light can act, and there are also other considerations regarding the kind of light which is effective as you reduce the size of the particles, which also is favourable for it.

Experiments I have made favour this theory, if theory it can be called, but I shall hope that fresh light may be thrown on the subject during the discussion.

NOTES ON GELATINE EMULSION.

BY COLONEL H. STUART WORTLEY.*

THERE are one or two points to which I wish to call attention with regard to red fog. That kind of fog was quite unknown to me in actual work, and I think I have been able to trace the reason. I have always used nitrate of uranium in my emulsions, but on one occasion lately, having omitted it, I found red fog. Two emulsions, treated in exactly the same way, were then tried, one with nitrate of uranium, and one without. Here is the result: red fog developed in one, not in the other: the plates showing clearly the fact.

I also wish to draw attention to the fact that a very powerful action is brought to bear on the gelatine by the silver. In this bottle is gelatine exposed to light with silver in: in this one collodion with silver in. Note the difference, and you will see how powerful an influence is exerted in one case, and not in the other.

Now, some years since I pointed out that washing collodion emulsion with hot water robbed it of some valuable property, and I now find that a very great deal of the varying results of gelatine work is due to variation in the washing. When exposing with Mr. Bennett the other day, I was struck by finding but little difference in the two plates—one prepared at considerable heat, one rather cool—and I feel sure that our plates were so much alike because we both wash according to what our plate requires.

I will go more carefully into this subject, and bring it forward again in the future. I believe that this question of washing greatly affects the keeping qualities of plates, as I remember that among some samples of plates that were sent round the world, after being exposed, to test their keeping qualities, one set developed quite perfectly, and this set had had a special method of washing.

I mentioned at the last meeting that I had tried all kinds of plates and formulas since Mr. Burgess first sent out his capital plates and emulsions in 1873, and that I had not found any plates equal to Mr. Bennett's, with the exception of those I prepared myself, and I think that the original starting-point of all us washed emulsion workers should now be reprinted. This, then, is from the *British Journal*, Nov. 14, 1873:—

"*Hints to Gelatine-Bromide Workers.*—I hope the following hints to gelatine-bromide workers will be found useful:—To make the gelatine-bromide emulsion, put half the gelatine to be used into one vessel, and the other half into another. Now pour as much bromide of cadmium solution into one of the vessels, and as much nitrate of silver solution 'measured' into the other, as will cover the gelatine. 'The strength of solutions will depend on the quantity of silver bromide required in the gelatine.' When the gelatine is swelled sufficiently, pour the solutions off and measure; by that means the quantity of bromide and silver taken up by the gelatine will be ascertained. Keep the bromide in excess of its equivalent of silver by adding bromide solution, if required. Heat both the quantities of gelatine until dissolved; then mix, stirring with a glass rod. Let it stand till cold, cut in slices with a piece of thin glass, and wash in distilled water, to remove the excess of bromide."—J. JOHNSTON.

It is only necessary to point out that here are the two great principles on which now much stress is laid: "Keep the bromide in excess," "Wash to remove the excess after solidifying it into pellicle." No such instruction had ever appeared before, though it reappeared six days afterwards in Mr. Kennett's Patent of Nov. 20.

A NOVEL ACCELERATOR.

A SOMEWHAT novel method of shortening exposures in the studio is claiming some attention in the United States. Mr. D. N. Carvalho, writing in *Anothony's Bulletin*, announces that he is able to reduce the exposure at the rate of from thirty-three to sixty per cent., simply by painting the whole interior of the studio, walls, doors, sashes, and floor one uniform tint, which he describes as "orange pea-green"! He materially shortens discussion on the subject by emphatically placing it as a matter of proved fact. He was quite prepared, he states, to find that his statement "would lead to controversy and doubt as to the correctness of it as a theory; and likewise, that sceptics and others should express their doubts of it as a matter of fact was also to be anticipated: all new discoveries, and more especially this one, in direct conflict as it is with all the accepted theories for the past thirty years or more, would, in the ordinary course of events, be subjected to the 'fire' of scientific and other opinions. This has in a great measure come to pass. 'Authority' after 'authority' have been placed before me, all bearing against the above statement; but, notwithstanding all this, it still remains an actual fact that a gallery painted of the 'orange pea-green' already mentioned will absolutely shorten exposure from thirty-three and a third to sixty per cent., according to circumstances. Not only this, but the shadows will be softer, the expression of the sitter's face more pleasant, there being no intense light to trouble the eyes; and, lastly, you need no change to be made in your regular chemicals, apparatus, &c. The matter ceased to be an experiment long ago, as my many letters from those who have been enabled to see through the 'spectacles of doubt,' and trying it, found, much to their surprise, that they could hang up (there to remain) the past thirty years of theory, and take to 'practical results'; more so, when about one-half time, or more, in 'exposure' was gained. Thus—"though a man convinced against his will is of the same opinion still," as quoted by some one, I don't remember who—in this case one must believe, because 'practice' proves itself always never failing."

The curious part of this singular announcement is, that it is fully confirmed by communications in the same journal from well known photographers of good standing. Amongst these are Mr. Estabrooke, of New York, and Mr. Ryder, of Cleveland. Mr. Bash, of New York, states he finds it enables him to reduce his exposure one-half; and Mr. E. Decker, of Cleveland, finds it permits a similar reduction. It has been proposed before to paint the interior of the studio blue, so as to secure the aid of adventitious light as an accelerator, and it has been proposed to paint the interior black, so as to secure brilliancy by shutting

off all adventitious light. But, until now, it has not been proposed, we think, to accelerate photographic action by colouring the interior of the studio with an essentially non-actinic colour. There is an old paradoxical saying to the effect that nothing is so certain as the improbable. The paradox seems to be verified by Mr. Carvalho's experience.

HYPOSULPHITE AS A THERAPEUTIC AGENT.

OUR transatlantic contemporary, *Anthony's Bulletin*, contains a communication from a correspondent proclaiming the rare virtues of hyposulphite of soda as cure for erysipelas. Medical men are familiar with the use of hyposulphite as a somewhat active aperient, and it is regarded by some as very valuable in removing impurities of the blood; but it has not come much into use in medicine. We place the new claim for it on record, but would caution our readers against experimenting with disease. Erysipelas is too dangerous a malady to be tampered with, and should be placed under the treatment of a competent medical man. We subjoin the communication in question:—

"I take pleasure in communicating the needed information concerning the virtues of hyposulphite of soda in erysipelas. Of course, when erysipelas proceeds from a wound it is more delicate to manage, and requires the best surgical skill; but when it is of the milder form, on the outside skin in the face or any other part of the body, proceed as follows:—Take of hyposulphite of soda any quantity, and make a saturated solution in a bottle of any convenient size—six, eight, or ten ounces. If the individual is a strong, hearty man, and the disease has a good start, give your patient one tablespoonful every hour for twelve hours; then decrease the dose, as the benefits become manifest, say once in three hours. It may cause diarrhoea; but never mind, it will destroy any febrile symptoms. Twenty-four hours is generally sufficient to produce a decided change for the better, unless it has six or seven days' start, in which case it will take longer. The results are generally so wonderful that I have never known the remedy to fail. With an old person you may substitute a teaspoonful for the tablespoonful, and once every two hours. You may put this down: that the sooner you can get a good quantity of the soda solution into the body, the sooner the trouble will be over. Now for an outward application: use equal parts of the soda solution and glycerine; saturate cotton flannel with the above, and lay on the part affected. Eat simple food—avoid all exciting food and drink; farinaceous diet is absolutely necessary. If you can bathe the part affected with the above solution, do so; then lay on the saturated cotton.

"Hypo is equally as efficacious in any poisons from insects or vegetables; old wounds in sores are soon healed by washing the parts in a solution of soda. It is also good in typhoid fever, carefully administered.

"Now if a person has a form of erysipelas that is not so decided, but (say) chronic, let him take a teaspoonful every night of the solution, and the disease will be entirely removed, if kept up for a month. The disease seldom or never attacks a person the second time when eradicated by the soda treatment.

"If any other information is needed, I shall be very much pleased to communicate, for I consider the foregoing has saved my life, and it has cured fifty persons in succession without fail right under my own supervision."

A MODIFIED IRON DEVELOPER.

MR. J. DE WITT BRINCKERHOFF, an old photographer in the States, gives in our New York contemporary a developer, of which he speaks in very high terms, as never fogging, however much pushed. It is a modification of a

developer some time ago published by Mr. Henderson. We now quote Mr. Brinckerhoff's own words.

Protosulph iron	3 ounces
Alum (pulv.)	5 "
Water	2 quarts

Filter, and, for use, add to each twelve ounces of the above half-an-ounce of acetic acid, No. 8. Alcohol is not required, unless the bath is highly charged, and when the developer does not flow evenly it is best to evaporate the alcohol and ether.

"I find this developer perfectly compatible with the bath solution, a few drops of which may with entire safety be poured on the plate at any stage of the development without fogging in the least, and any intensity gained that is required; but with proper exposure all the detail is brought out, resulting in a perfect printing negative, without any continuator being necessary."

A PHOTOGRAPHIC PARADOX.

BY CAPT. ABNEY, R.E., F.R.S.

THE above is the heading of a leader in the last issue of the PHOTOGRAPHIC NEWS, and, as the Editor implies, like most paradoxes, it is only one in appearance. Mr. C. S. Murray states correctly Mr. Cooper's dictum regarding the proportionate exposures necessary to give gelatino-bromide plates and wet plates in different lights, and he also correctly states my opinion as to the cause, though he fails to see exactly what I intended. I will try and explain. Is it true that a gelatine plate can be a thousand times more rapid than an ordinary wet plate? It looks admirable on paper to state that such gelatine plates exist, and it is perfectly true that they are extant, and if, instead of a thousand times more rapid, I were to say infinitely more rapid in both cases, I should still be telling the truth—but not all.

We have heard of the late Mr. Claudet taking a sensitive Daguerreotype plate into his studio and exposing it to the light that penetrated into it, and on developing such a plate found no trace of the action of light. This, as it stands, is true, and yet only partly true, for the kind of light that penetrated into the studio is not stated; but when it is known that the light was that which pierced through a dense London fog, the wonder ceases. Had Claudet taken a gelatine plate into the studio at the same time as he took the Daguerreotype plate, and developed it, he would not have found the plate free from evidence of the action of light. If the light which always had access to our plates was such as came through a London fog, it would be exact to say that a gelatine plate was infinitely more sensitive than a Daguerreotype plate. The same argument applies to the gelatine plates and those prepared by the wet process.

Now we come to the fact that the former have a greater proportionate advantage in winter than they have in summer. It has been my fate to have a good deal to do with photographing the spectrum at all seasons of the year, and in winter the blue rays are largely deficient as compared with the yellow and green rays, taking their proportion as existing in the light of a bright spring day. It is a well-known fact that aqueous vapour cuts off the blue and the upper part of the spectrum: the more vapour present and the greater thickness of atmosphere through which the light has to travel, the more this part of the spectrum is absorbed. In winter the air is, as a rule, more charged with aqueous vapour, and the altitude of the sun is many degrees less than in summer. Hence we have a reason for the less proportion of blue rays in the former than in the latter season, in comparison with the yellow and green rays, which are not cut off to nearly the same extent by the above causes.

For the sake of example, let us suppose that the relative chemical activity on silver bromide of the chemically

active rays of the spectrum on a summer's day, when empirically divided into yellow, green, blue, violet, and ultra violet, are—

Yellow	Green	Blue	Violet	Ultra Violet
10	40	100	100	10

and that in winter all the ultra-violet, $\frac{1}{20}$ of the violet, $\frac{1}{10}$ of the blue, $\frac{1}{4}$ of the green, and $\frac{1}{2}$ the yellow rays are cut off; then the relative value of chemical activities would be—

Yellow	Green	Blue	Violet	Ultra Violet
5	10	10	5	0

In summer the total activity would be 260, and in winter 30.

For a wet plate the chemical activities would be confined to the blue, violet, and ultra violet. In summer, therefore, the total chemical activity for it might be 210, and in winter 15.

The relative values of a wet plate to a gelatine plate would be in summer as 10 to 8 nearly, and in winter as 10 to 5.

In reality, the absorption is much more than the above, and photometric measurements of light on a winter's and summer's day show that the light is very much yellower on the former than on the latter.

The British Association has appointed a committee to fix a standard of white light, and when our labours are concluded it will be easy to show in a proper manner that what is now considered as white light may be very yellow or very blue as compared with the standard. The blue rays do not neutralize the action of the yellow rays, as Mr. Murray suggests. I think I have conclusively shown in previous experiments that what used to be called the antagonism of different rays is non-existent; and let me suggest that to glaze the studio with yellow glass would be a worse than useless expense.

In the column headed "Photography In and Out of the Studio" for last week I see the writer has given Messrs. Bolton and Sayce the credit for the introduction of the gelatine emulsion.* It should be given to Dr. Maddox and Mr. Burgess, if I am rightly informed.

GLASS SUITABLE FOR DARK ROOM WINDOW

BY W. BEDFORD.†

THERE are one or two points in Captain Abney's paper read at the last meeting I should like briefly to touch upon, as, owing to the adjournment of the discussion, I have had the opportunity of making a few experiments in a similar direction, and I now lay the result before the meeting.

I believe I am right in surmising that Captain Abney, in photographing the absorption spectra of the various coloured glasses employed, made use of a single thickness only in each case, and gave the same exposure to each, without reference to the quantity of light transmitted, and in making a practical selection from them it is essential to bear this in mind.

In my own experiments I have confined myself to the trial of four different samples of glass, viz., orange, stained red, ruby, and deep ruby. The first-named is mounted in one, two, and three several thicknesses, and the deep ruby may be reckoned as equivalent to two thicknesses of the ordinary.

Now, to pass on to the results. With bromo-iodide wet collodion, the single orange is undoubtedly the first to fog, closely followed by stained red, and then ruby; but it will be seen that the two thicknesses of orange are far superior to the ruby in absorbing the actinic rays, and at the same time transmit more of the luminous rays, while the three orange and deep ruby have each, during this exposure, intercepted the actinic rays sufficiently to prevent reduction. The other

* Our contributor, in speaking of the origin of the gelatine emulsion process, was doubtless thinking of the collodio-bromide process, which was introduced by Messrs. Sayce and Bolton. The origin of the gelatine process is not absolutely decided. Some claim it for Mr. Kennett. A gelatine emulsion with chloride of silver was patented in 1865.—Ed.

† Read before the Photographic Society of Great Britain.

negative is developed on collodion bromide (and the effect is the same on gelatine bromide): it is evident here also that the ruby glasses possess no advantage over the two and three thicknesses of orange glass respectively.

Of course, it must be understood that I do not for a moment call in question Captain Abney's results, which, indeed, are fully corroborated by these rough experiments. I would only urge that it is unnecessary to submit to the trying glare of ruby-coloured light, when we can avail ourselves of one of which is far more agreeable to the eyes, and equally efficacious.

GELATINE PLATES IN THE STUDIO.

BY SAMUEL FRY.*

THE very interesting discussion of last meeting, and the remarkable nature of the results shown, induced me to extend the experiments I had already made, and to at once institute very careful trials. The large proportion of the weather since then has been bad, but during the brief period of fine days I have had a great success. I believe I shall not use collodion and the bath again, unless unexpected difficulties arise. The exposure is about one-sixth that of wet collodion, and no difficulties attend development. I had, before going into the practice on any scale, witnessed the operations of others, and was much discouraged by finding they worked in a room so extremely dark as to be miserable in the last degree. I am able to say this is entirely needless. In my laboratory, which is a large apartment, are two windows about 6 by 4 feet. These are covered with four thicknesses of the well-known thick yellow paper, leaving abundant light for all purposes, and quite harmless to the plates. It is a great relief to have no smell of collodion or cyanide, and to be able to conduct the development without soiling the fingers. The tendency of these plates is to run to half tone, whilst collodion has just the opposite inclination.

A remark was made at the last meeting by our old friend, Mr. Francis Bedford, which much impressed me. "How," said he, "will you manage when you want to bring up some faulty part of the negative, and give it more force?" I may reply to this, that the effects seen on these plates are more equable, and more just in their proportions of effects, than is generally found in collodion work. In fact, they do not require that separate parts shall be reinforced, the correct gradations being a striking characteristic of the system.

I find I must prepare my own plates, and, thanks to Mr. Bennett, who has so generously given this process, there will, I am told, be no special difficulty. By this method you get rid of plate-cleaning, albumenizing, collodion, nitrate bath, and cyanide. The saving of time is enormous, and the quality and rapidity invaluable.

Correspondence.

ARTIFICIAL LIGHTING.

SIR,—Mr. Harman need scarcely ask if he is again perverting my meaning, because it must be palpable to every thoughtful reader of my recent letter on the above subject that he is again doing so in stating that when taking certain chance customers on dark days, I occasionally found it desirable (in order to secure prepayment, and, consequently, reappearance, for another sitting) to show them the under-exposed negative, which I contend, and presume Mr. Harman will not deny, is equivalent to showing them a positive. I say, in stating this—though I did not deem it necessary to enter so minutely into details in order to make myself understood by the most ordinarily intelligent photographer—I did not infer that I did a "positive" trade, as Mr. Harman's remarks would suggest; on the contrary, I can, with that gentleman, claim the honour

* Read before the Photographic Society of Great Britain.

(if such it be—certainly such he considers it) of total exemption from that class of business, both as regards the past as well as the present. As for there being anything degrading in the occasional practice of what I consider a most justifiable "trick," I must leave it to all common-sense business men to judge, more especially those who have had dealings with uncertain sitters, and wasted their time and material for nothing. If Mr. Harman has had no such painful experiences, he is to be congratulated.—
Yours faithfully,
VINCENT HATCH.

ARTIFICIAL LIGHT PHOTOGRAPHY.

DEAR SIR,—I am pleased to see that my letter on the above subject has been taken up, and served to ventilate the subject more fully, which tends to prove that there are two sides to every question, and I, in my zeal in advocating one side—that of perfecting what we do know—have neglected the other side—that of experimental research. But I would not for a moment have any one to think that I am opposed to any innovation or additions to our knowledge which increases the usefulness of, or is any improvement to, our art; in fact, I think the tenor of my letter partook of a call on photographers to improve their work artistically, not to work so mechanically, just putting a sitter against the head-rest, exposing a plate, "your name and address, please," and perhaps money, and so the matter ends.

Now there is a wide difference, as you know, sir, between exposing a plate in the camera, and taking a "picture;" and one idea in my mind, when penning my letter to you, was, that this artificial light just provided the means of giving an image on the sensitive plate, and that was all, at least in most hands, as it must be more difficult to make a "picture" by the artificial light than by daylight, so that thus these "plate exposers" would be multiplied to the detriment of the art, for, being carried away, also, by the novelty of making negatives by the artificial light—the main point of which is, I presume, to get an image at all—they would lose sight of artistic excellence. More still, I also took exception to the expense. Well, that plea must go to the wall, as it has been shown that artificial actinic light can be produced for a mere trifle by these pyrotechnic compounds, and more effectual and certain than the costly electric light. But I will not review all that has been written by your correspondents and by yourself relative to my letter; suffice to say that I have read and noted them all, and benefited thereby, all of which shows, as I have written before, that there are two sides to the question; for who knows where this experimental research may end? There doubtless will be some benefit derived. Perhaps great results may lead therefrom; for instance, although it may be very Utopian to fancy that it might lead to the discovery of photography in colours, it might. How, I cannot say; for by the present means and tools it seems as far off as ever, and fresh ground will have to be broken. *Apropos* of this, Swan's dry plates appear to be more sensitive to yellow or dull rays than to the rays that are generally considered most powerful on the sensitive plate, and these may be eventually the bye-roads—perhaps the high-roads—to such a consumation, just as past research has been to the art's present efficiency, which the profession, through the artificial light, seem to be in danger of deserting, and which, in my letter, I advised them not to do, similar to the advice you gave last week, not to throw old discarded silver baths away, in case the dry plates do not answer so well in the summer light.

But Mr. A. Clarke, in your last issue, quotes part of my letter, which I must note, as to the characteristics of pictures taken by the artificial light, namely, they having "unnatural waxy skin, glassy eyes," &c. Well, all I have seen were so; but they were taken by the electric light, some time ago, and no doubt improvements by the

means of reflectors and diffusers of the light, to give softer effects, have been devised, so as to make them produce a different class of picture to what I saw and described, of which you say "There is nothing to distinguish them from ordinary good work by daylight," which remark I have not seen in the NEWS, and have not the back numbers by me at present. But still, none would use artificial light when they could procure daylight, no more than anyone would shelter a garden from rain and water with hose and tap-water; and I do not dispute that there are occasions when it would come in usefully, just as the hose, &c., do in a dry season. Mr. A. Clarke gives an instance at the faucy dress ball, where being photographed would be one of the chief items of the programme, through its novelty; and if the possibility was wider known, it would be somewhat of an incentive to holding faucy-dress balls, and might be even called in at ordinary parties and balls. But the principal reason why I must notice Mr. A. Clarke is that he accuses me of "judiciously" concealing my name under a *nom-de-plume*, namely, "Decor Inemptus," at which I feel somewhat nettled, and so beg to sign myself.—Yours truly,
W. BARRY.

Hull.

HOW TO STEADY A CAMERA IN WINDY WEATHER.

SIR,—I beg to forward the following for insertion in the NEWS:—Procure two pieces of stout iron wire about twelve inches long; bend one end of each into the form of a hook, and sharpen the other to a point. To use them, push the pointed end of one wire into the ground at an angle of about 45°, immediately under the camera; do the same with the other wire, but in the opposite direction, so that when in position the two hooks will be side by side, thus forming a kind of bridge, which would require a very strong upward pressure to remove. Now get a stout piece of string; make a loop at one end, and slip it over the screw which fastens the camera to the tripod. The other end should then be fastened by a few turns round the hooks, pulling it tightly before making the final fastening.

I got this idea from an artist, who used the hooks to steady his easel, and I have since found it of great use for the purpose I have named.—I am, sir, yours truly,
Westcott, Dorking.

CHAS. BROWN.

PHOTOGRAPHS BY COAL GAS-LIGHT.

DEAR SIR,—Since my first essay at portraiture by gas-light, described in last week's NEWS, I have had the Wigham burner fixed in my own gallery, and have already succeeded in taking portraits with a moderate exposure. When the burner was fixed ready for use on Wednesday last, I at once saw that the gas had not previously been sufficiently turned on to attain the highest degree of illumination. With the gas at full cock and by the use of special and carefully prepared chemicals, the exposure was reduced one half. By a readjustment of reflectors, I still further shortened the exposure. The wet process used was that of M. Boissonas, of Geneva, the genuine formula for which I have only recently received from himself.

I am alive to the sensitiveness of gelatine emulsion, and have tried Swan's plates. They are exceedingly valuable for this new class of work.

Having written for any suggestion that Mr. Wigham might have to offer, he advises the use of his sixty-eight jet burner as giving a white intense light, more than three times the illuminating power of the one I am using. It is probable that the actinic power is also proportionally increased.

In these experiments I have been greatly aided by Mr. Halliday, of Newcastle, who has introduced this burner into the North of England, the price of it being £5.

Enclosed you will find as many cartes as I have by me, some of them taken in one minute. The gentleman in the soft felt hat called by request to see the light. I had no intention of taking him, but when he sat on the chair just vacated by the lady with hat, I was so struck by the lighting, that I at once secured a negative. It is very likely that I may try the larger burner, if so, will let you know with what success.—I am, sir, yours truly,
P. M. LAWS.

PS.—I purpose writing you specially of M. Boissonas, and my opinion of his process.

[We shall be pleased to hear again from our correspondent, both on the gas-light portraiture and the process of M. Boissonas. The examples of gas-light portraiture, enclosed are admirable.—Ed.]

Proceedings of Societies.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE sixth ordinary meeting of the session was held in 5 St. Andrew Square, on Wednesday, the 2nd inst., JOHN LESSELS, Esq., President, in the chair.

The minutes of the previous meeting having been approved, the following gentlemen were unanimously elected ordinary members of the Society:—Messrs. J. B. Lawson, L.A., and Mr. W. Balfour.

DR. ALEXANDER HUNTER then read a paper on the selection of subjects from nature suited for photography (see page 183) the paper was illustrated by a very large collection of Indian photographs, many of them of a highly interesting nature.

THE PRESIDENT thanked Dr. Hunter for submitting to the Society such a large, interesting, and varied collection of photographs, the results of his own labours in India, and for the large amount of information concerning Indian life and manners.

MR. W. NEILSON doubted if landscape photography was more difficult than that of portraiture. A prolonged experience as a professional portrait photographer had confirmed him in the belief that the latter was the most difficult branch of the art. He recommended landscape photographers to discard the cumbrous appliances necessitated by adopting the larger sizes for landscape negatives, and strongly urged the desirability of taking perfect small negatives, which, with the extremely rapid exposures now possible, enabled the photographer to secure figure and cloud as they were in nature, without the necessity of resorting to combination printing; the gelatine film, being so structureless, would bear any reasonable enlarging without deterioration, and the resulting large pictures would be far superior to similar sizes taken direct from nature, besides being produced with less trouble and expense.

MR. W. H. DAVIES reminded members that Mr. Lindon Smith had been famous for his landscapes with mist and cloud, and for his beautiful results had obtained a medal from the Photographic Society of Scotland. Dr. Silvey had also made a speciality of landscapes taken during rain, and some of his chief works owed their peculiar charm to this condition.

MR. JAMES HOWIE considered that as the chief beauty of all photographs consisted in the minuteness of the rendered details, the presence of mist and fog could be nothing but deleterious, and he believed that distant objects must most materially suffer.

DR. THOMPSON, R.N., said that he believed the cause of the peculiar beauty of many pictures taken in rainy weather might be traced to the fact that when the air was charged with moisture it contained less floating particles to obstruct definition. It was proverbial that in a dense state of the atmosphere distant objects looked near, or, in other words, were more clearly or definitely seen.

MR. M. G. DOBBIE thanked Dr. Hunter for so kindly responding to his request to provide matter for that evening, and congratulated the Society on possessing a member that had done such important services for art and art education in the Indian empire. He proposed a vote of thanks to Dr. Hunter, which was heartily accorded.

MR. JAMES CRIGHTON exhibited a series of Chinese photographs, consisting of landscapes, architecture, and domestic scenes, which were examined with much interest.

The following two questions were found in the question box:—
1. What is the best filtering material for gelatine solution?

2. What is the best means to get brilliant prints from very thin negatives?

1. In reply to the first, it was elicited that sponge and glass-wool had been employed with success, but for ordinary emulsion work it was merely necessary to tie a piece of muslin over the mouth of the containing vessel, allowing the emulsion to run through this on to the plate; the muslin effectually prevents the passage of solid particles and the occurrence of air-bubbles. A small hole must be provided for the admission of air. To remove the yellowish tint inherent to some gelatine films, it was recommended to decolourize the gelatine by means of clean lumps of fresh animal charcoal.

2. A highly salted paper, sensitized on a strong silver bath, exposed under the negative in a very subdued light, so as to take a long time to print, was said to be the best for thin negatives. Some found fuming the paper with ammonia to be an improvement.

Notes of thanks to Mr. Crighton and the President terminated the proceedings.

PHOTOGRAPHIC SOCIETY OF BERLIN.

At the meeting of the 6th February last, Herr C. BRASCH, President of the Society, in the chair,

Herr E. DUBY delivered a lecture on "Artificial Light for Photographic Purposes," illustrated by experimental demonstrations. The principal requirements of such light are, as he pointed out, that it must be as rich as possible in the chemically active rays. The light from common coal gas can be improved by making the gas, before it reaches the burner, pass through a U-shaped tube fitted with loose cotton wool which has been steeped in naphtha, benzine, or paraffin. A stronger and highly actinic light is obtained by burning easily combustible substances, such as sulphur and phosphorus in pure oxygen gas. A mixture of the vapour of carbon disulphide and nitric oxide, or oxygen alone, burns with a bright flame, which is rich in the chemically active rays; but, in spite of every precaution, the mixture is liable to explode. For practical purposes the light devised by Haruecker is very valuable; this is a modification of the ordinary oxy-calcium light with coal gas, where the vapour of alcohol is substituted for the latter substance. To produce a still brighter light a jet of pure oxygen gas may be passed through burning hydrogen, and the resulting highly heated flame directed on a cylinder of lime or magnesia. In conclusion, the lecturer exhibited the light obtained by burning the metal magnesium; this is an excessively actinic and intense light, but is attended with the disadvantage of being very costly, while, as yet, no satisfactory lamp has been devised for burning the magnesium regularly. Three different kinds of shutter for the objective were exhibited and compared. The first of these, by Vogler, is set in motion by the pull of a string, and is distinguished for its simplicity and cheapness; the second, the well-known pneumatic shutter of Cadett, is expensive, and, as was objected by one of the members present, is apt to startle the sitter on being sprung open; in the third, the invention of Herr Grundner, the last named difficulty is obviated by causing the shutter to move within the instrument, but a fear was expressed that the principles of its construction would infringe the patent of Cadett.

The next meeting was held on the 20th February, when Herr C. BRASCH again presided.

Herr E. DUBY gave a lecture on "Oxygen, the Methods of its Preparation, and its Importance in Photographic Work," at the end of which he exhibited a new oxy-hydrogen burner for use with ordinary coal gas, giving a very bright light, which was highly approved. When the cheaper method of obtaining oxygen described in the lecture shall have come into general use, there is no doubt that this burner will be extensively employed.

Apropos of oxygen, Herr HAMMER, the chemist, who was present at the meeting, gave an interesting account of the liquefaction of that gas.

With reference to the exhibition of the oxy-hydrogen light, Herr TH. JOOP inquired whether an oxy-paraffin lamp could not be constructed. The lecturer replied that lamps of the kind indicated had already been made, but that they gave no satisfactory result; without a chimney they were apt to smoke, and if a chimney were used it would be sure to fly. Though the first of these defects might be mitigated by adding naphtha to

the paraffin, and the second by the use of toughened glass chimnies, still some good substitute must be found for paraffin before lamps of this sort could be brought into use. Under no circumstances should ligroin be used in a lamp, on account of its explosiveness.

Herr JUNK submitted to the notice of the meeting a number of positives taken by him by means of the carbon process; the opinion was unanimously expressed that these pictures would bear comparison with any produced in the same way.

Herr C. SUCK stated that he had taken positives both by the emulsion and by the tannin process, and that he preferred the latter for enlargement purposes, as the positives obtained by that means possessed greater transparency. With respect to the tannin process, the views of the meeting appeared to be that the dry plates produced by it were not very permanent, in consequence of tannin being an unstable compound which is apt to be converted into the less energetic ferrotannic acid. It was also complained that the silver iodide film was apt to detach itself from the glass plate; but as a remedy for this defect, Dr. STINDE recommended warming the plate before developing.

Dr. STOLZE recommended dry plates with coffee, as possessing much greater durability.

Some of the pictures taken by M. BOISSONAS, of Geneva, with his "extra-rapid" process, had been sent for exhibition, and were pronounced to be really "instantaneous views." With reference to this subject, a question was asked as to the so-called instantaneous process of Herr Fricke, in reply to which Herren GERICKE and VÖGLER, each of whom had purchased the licence, declared that they had found it to work no quicker than their own chemicals.

PHOTOGRAPHIC SOCIETY OF VIENNA.

An ordinary meeting was held on the 18th February, Dr. E. HORNIG, president of the Society, in the chair.

Herr MARTIN, Imperial Counsellor, exhibited some of the solar photographs taken at the Observatory of Moudon by M. Janssen, and addressed some remarks to the meeting on the subject. These remarks were to a certain extent a reproduction of the notice in the *Comptes Rendus*, as the photographs had arrived in Vienna without any accompanying explanations. Janssen has succeeded in producing these intensely interesting and instructive photographs by reducing the exposure to the extremely short duration of 1/3000th of a second, at the same time producing the picture on a very large scale; those exhibited at the meeting were on the scale of 1.38 metre for the diameter of the sun's disc. The short exposure is obtained by causing a screen with a small aperture to pass by means of a spring with extreme rapidity in front of the eyepiece of the telescope used as the photo-heliograph.

It is well known that the sun's surface, when viewed through a telescope, appears to be covered with granules, which may be compared to grains of rice lying close together on a plane surface. This granular appearance is seen quite plainly in the photographs, and when they are looked at with the light at some distance, there will be observed spots of greater and of less sharpness, which seem to stream out beside each other in vortex figures. The disturbed and quiescent parts of the solar surface can be distinctly recognized by the different intensities of the radiation; this variation in intensity is only shown in consequence of the shortness of the exposure, for with a longer duration of exposure the whole face of the sun would appear equally white in a photographic positive, and dark in a negative. The speaker went on to explain the external constitution of the sun, which, as far as known, consists of the photosphere, the reversing layer, the chromosphere, and the corona; and also the photographic experiments of Dr. Draper, by which he believed that he had proved the presence of oxygen in the solar atmosphere. According to Janssen's own views, the mere fact of the great diversity of form of the granulations in the photosphere tends to show that these elements consist of a very mobile substance, which easily yields to external influences. This is a property of a fluid or gaseous condition; other considerations, however, lead to the conclusion that the condition of the granulations is analogous to that of the clouds in our own atmosphere—that is, that they consist of a solid or liquid substance in a state of fine subdivision floating in a gaseous medium. In the course of his observations Herr Martin alluded to the urgent necessity for the establishment of an observatory in Vienna for experimental

solar research by photography, and recommended the Society most strongly to keep this object in view.

The PRESIDENT, in thanking Herr Martin for his interesting discourse, remarked that the idea of a photographic observatory in Vienna was one with which he had been familiar for years; but he feared, however, that the position of the Society was not yet such as to warrant it in entering on an undertaking of so great magnitude, and times were not just now propitious for claiming State aid. From another quarter, however, he had hopes of attaining assistance towards the realisation of the project, the details of which he was not just then at liberty to explain. He had, consequently, strong hopes that, if not during the present year, at least within a very short time, steps would be taken towards the foundation of such an institution, and so soon as something certain had been decided on, he hoped to be the first to communicate the particulars to the Society.

Herr LUCKHARDT seized the opportunity of offering to their President the congratulations of the Society on the high distinction he had obtained by the Emperor's conferring on him the order of the Iron Crown.

Dr. HORNIG, in returning thanks, assured the members that he had always to the best of his knowledge and ability worked for the interests of the Society, and would still continue to do so; by reason, however, of his continued ill-health, and on account of other engagements, he must claim the indulgence and active assistance of all his fellow-memors.

In a discussion on the question where the best dry plates for landscape views could be obtained, the President remarked that the great majority of photographers in Austria employed exclusively the wet process; and that the few who occasionally resorted to the dry process were in the habit of preparing their own plates. One great hindrance to the importation of dry plates from abroad was the regulations of the Custom-House, so that the trade in these plates, so far as the Austrian Empire was concerned, was a very small one. In England there appeared to be a great traffic in dry plates, the manufacture of which had been undertaken by special houses, probably in consequence of the large number of amateurs who pursue photography as an amusement.

Herr VON MELINGO believed the subject to be well worthy of the attention of the Society; he had himself been often put to straits for want of an establishment where he could obtain reliable dry plates. He expressed a wish to know whether at the dealers in photographic requisites there was a great demand for dry plates; and in reply,

Herr KIRSCH stated that the customers of the firm of A. Moll and Co., for these articles, were very few. Since then this house has been appointed sole agents for Austro-Hungary, for the gelatine emulsion plates of Messrs. Wratten and Wainwright.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

At a recent meeting President NEWTON in the chair, the minutes of the last meeting were read and confirmed.

After some routine business the PRESIDENT exhibited to the Section a print or photograph as a curiosity, and said: What gives it interest is the fact that it is printed on paper sensitized three years and nine months since. I found one peculiarity about the paper. It would break when bent at a short angle; when put in water, however, it assumed its normal condition of toughness. After the paper is sensitized in the ordinary way and hung up, as soon as it stops dropping, wipe the silver off the bottom, before it begins to curl at the edges, and lay it back down on a dish of water containing one ounce of hydrochloric acid to forty ounces of water.

The PRESIDENT also exhibited to the Section two prints from negatives and said: The negatives were made with an emulsion that was nearly two years old—not quite as old as the paper, but it will be two years old in the Spring. The important fact about it is that it has not deteriorated in sensitiveness. It is just as sensitive as emulsion made only a week since. Of course these facts we can only demonstrate by time. We cannot determine the keeping qualities of emulsion by theory to any extent; but that this emulsion is just as sensitive as it was a year and a half since is to me a very important fact; that we can have an emulsion which will respond at any time to one's wish, and have no fear of it playing any of the old bath tricks, is exceedingly satisfactory.

Mr. CHAPMAN. Was this emulsion you speak of ever in the foggy condition, and had been reclaimed?

The PRESIDENT. I cannot answer that question positively. My impression, however, is, that it was never in a foggy condition.

Mr. CHAPMAN. I found nearly all the emulsion that went over into that condition, or passed beyond its best condition, without chloride being added to it sufficiently to restore it to its normal state, continued to become slower and slower. That has been my experience; but an emulsion prepared just as it should be, not to be restored or brought back, will remain as it is.

Mr. NEWTON. That may be so. I have emulsions two years old that retain their good qualities. I would rather work an emulsion a year old than one made recently.

After some further conversation the proceedings terminated.

Talk in the Studio.

OIL COLOURING.—We are occasionally consulted by correspondents who require the aid of artists for colouring, but generally find it difficult to give advice. We may remark, however, that we have recently seen some examples of colouring in oil on enlargements, which appeared to us to be very excellent and artistic work. The painting was executed by Mr. E. Sawyer, of Newcastle-on-Tyne, who is, we understand, settling in London with a view to executing such work for photographers. We believe the work will be good, and the artist trustworthy.

"THE DRUGGISTS' ADVERTISER."—We are requested by the Editor of this journal, from which we have occasionally made interesting extracts, to say that having undertaken important business duties, the issue of the journal will cease.

A SUPPOSED NEW DEVELOPER.—The Editor of the *Society's Journal* says:—"Mr. J. R. Clarke, of Thirsk, writing to the *Photographic News*, communicates a developer for dry plates, which is made as follows:—"To twelve ounces of boiling water, and three ounces of salt of tartar (to this while hot), add oxalic acid until effervescence ceases; if found too acid, add a little more salt of tartar until about neutral; this is a stock solution which will keep. To make the developer, add to each ounce of the above about 20 grains of photosulphate of iron (ferrous sulphate)." Mr. Clarke says that the advantage of this over the ferrous oxalate developer is, that it will keep for a month or more; it develops quicker, and after the iron is added, it will keep in good developing action for three or four days. Salt of tartar is really potassium carbonate, and Mr. Clarke, by adding the oxalic acid, produces the neutral potassium oxalate, so that we have in reality ferrous sulphate added to neutral potassium oxalate to form the developer. A simpler plan is to get the neutral oxalate and add the iron salt directly to it. As a developer it is excellent, and we have frequently used ferrous oxalate by adopting the following plan:—Saturated solutions of potassium oxalate and ferrous sulphate are made, and the latter added to the former in equal proportions; the result is a developer which is not quite so active as that already given in the pages of the *Journal*."

A CONVENIENT PLAN FOR WASHING GELATINE EMULSIONS.—In Mr. Bennett's process a rather inconvenient plan of washing the gelatine emulsion is prescribed, and one on which we think we have improved, since by adopting it the emulsion can be washed in an ordinarily lighted room. A bottle by preference having a wide neck is chosen, and a tin canister with a top is procured, into which the bottle can be placed and covered up. In the top a hole is carefully drilled so as just to fit a piece of $\frac{1}{4}$ -inch glass tubing, $\frac{1}{2}$ inch longer than the canister is high; and about 2 inches from the bottom another hole is bored, and a $\frac{1}{2}$ -inch tin tube with a couple of bends at right angles to one another soldered over the hole. The bottle with the emulsion in it is placed in the canister, the glass tube put into the bottle through the hole in the lid, and a piece of india-rubber tubing slipped over the projecting end of the tube till it fits tightly against the lid. The other end of the india-rubber tubing is fitted to the water supply, and the amount of water admitted to the bottle regulated by a clip on the tube or by the tap. We have ourselves used as a reservoir a 4-gallon jar with a hung-hole at the bottom; into the bung a piece of glass tubing is inserted as an exit for the water, and the supply is controlled by a clip on the india-rubber tubing. It answered excellently: four times filling washed the emulsion perfectly.—*Ibid.*

PHOTOGRAPHY AS A DETECTIVE.—Some correspondence has lately appeared in the *Times* on the failure of photography in thief catching. The following letter in the same journal makes some suggestions on the subject:—"In a letter from Mr. Fenwick, which appeared in the *Times* a few days ago, mention is made of the unsatisfactory results obtained in the photographing of convicts. Allow me to suggest that the camera and accessories used in photography being only receivers and not producers, the whole performance for a likeness occurs in front of the camera—i.e., on the face of the sitter, and by a studied appliance of the light. Therefore, the best means for arriving at a good result should be to photograph the convicts when they show their natural faces. By a very simple contrivance their likenesses could be taken unawares, and then the collection of portraits would be really useful. Another point of equally great importance would be to represent the convict either with a beard added to the portrait or suppressed from it, moustaches or no moustaches, alterations in the shape or colour of the hair, changes in the forehead, &c. This could be realized by a series of small masks, which would allow the police to see at a glance the same face with all possible changes. I refrain from trespassing on your valuable space to enter into a full description of the whole system proposed.—Your obedient servant,
SOL."

A NEW LIGHT GUN.—*Punch* says:—"Gentlemen of the Gun Club, it may perhaps interest you to know that a French Captain, M. Vassel, has proposed, in *La Nature*, an idea, said to have been originally conceived by M. Marey, of a 'photographic gun.' As you may suppose, this invention is so named from being designed 'for fixing birds in their flight.' This gun, which is fitted with Bertsch's automatic camera-obscura, is actuated by means of a trigger, but this trigger, instead of the usual action, releases a rectangular sliding screen, which has a round aperture in the centre to let the light pass, whilst it intercepts its two extremities. Should it be desired to produce at one operation a series of successive attitudes, the construction of a "photographic revolver" would offer no greater difficulty than the gun described. There, Gentlemen and Sportsmen, is a kind of gun by which you may be enabled to shoot live birds on the wing without hurting them. You bring down their photographs, and not themselves, but of course it must require at least as steady and skilful an aim to photograph them as it does to shoot them, so that the sport is all the same; and as for the fair damsels who countenance your exploits by their charming presence, they would surely derive additional enjoyment from seeing you hit off the pretty pigeons without killing them."

HOW ANOTHER MARTYR PUT IT.—"A little too much repose about the mouth for it to be natural," was the remark of a husband to a West-end photographer who had taken his wife's photograph.—*Family Herald*.

To Correspondents.

HAKMAN.—We cannot learn that any further experiments were made with junoniate of silver for photography. We think it is probable that if Sir John Herschel had done anything further in the matter we should have heard, as he was in the habit of occasionally corresponding with the *PHOTOGRAPHIC NEWS*. The salt is not, we think, in commerce. You will note that it is spoken of as being as sensitive as bromide of silver, not more so. Exceeding sensitiveness necessarily involves liability to fog. 2. We shall be glad to hear details of your experiments with gelatino-chloride of silver, and to see results. We shall have pleasure in trying it. Upwards of a dozen years ago Mr. Palmer worked in this direction with moderate success; and about the same time a patent was taken in this country for such a process; but it never came into popular use. Whilst engaged in working out our collodio-chloride process we tried gelatine with only partial success, the sample of gelatine we used having been, we think, had, as the film sometimes dissolved in a cold fixing solution. The "sandy" surface to which you refer we have attributed to excess of free nitrate of silver. 3. The heat bromide for emulsions has been a matter of some discussion. It is dependant chiefly upon which is most trustworthy for the precise proportion of bromine it contains. Dr. Eder recommends the double bromide of ammonium and cadmium. 4. You will see that the question of time and heat in regard to the maturity of emulsions was discussed at the last meeting of the Photographic Society. Our own experience is too limited and too much confined to experimental operations to be of authority.

J. R. W.—You are right in your conjecture; it should be oxalate of potash. You will find the method stated more fully in Capt. Abney's little work on emulsions.

SPRING.—You cannot very well combine in one lens and camera best suited for landscape work and portraiture. A bellows-bodied folding camera is most convenient for field work, and will answer for portraiture; but a portrait lens is best for portraiture, and is certainly not best for views. If you use it well stopped down, it may answer for some subjects. We cannot with propriety recommend makers by name in this column; if you will send a list of those you wish to select from, attaching a figure to each, we can indicate by the figure that we most recommend.

J. N. Z. D.—There is nothing to prevent you from becoming a member of the Photographic Society of Great Britain. The terms of subscription are one guinea admission fee, and one guinea per annum. According to the rules, however, gentlemen residing abroad are exempt from annual subscriptions after the first has been paid; but they are also exempt from the receipt of the Journal and of presentation prints. If you wish, therefore, to receive the journals and presentation prints, you will have to continue subscription of a guinea annually.

VICTORIAN AMATEUR.—The chief defect in the example of portraiture you enclose is the presence of ribbed markings crossing the picture diagonally. This is due to the glutinous character of the collodion, arising either from the use of an unsuitable sample of pyroxyline, or to excess of alcohol, or the use of alcohol containing too much water. 2. There are appliances for aiding in mounting, but we do not know of anything more effective than careful hand mounting. There are trimming knives which facilitate neat trimming of the prints. We do not know the price, but most dealers will supply them. 3. There are several excellent samples of collodion in the market, which you will find mentioned in our advertising pages.

FREDERICK C.—We are very sorry for you. As you will see, we have ordered the insertion of the advertisement.

W. AINSWORTH.—Your letter was forwarded as desired.

HERBERT H. LANE.—We are sorry that no successful issue was reached. We are sorry that we do not know the address in question. Your envelope, open at the ends, was marked by the Post Office authorities as "containing a communication in the nature of a letter," and charged extra letter postage.

REVERSED NEGATIVES.—Referring to this subject, our correspondent, J. L., writes:—"In my communication respecting the date when Mr. Dallas first suggested reversed negatives, I wrote by mistake 1863 instead of 1862. If you will kindly correct the error, you will much oblige, yours truly,
J. L."

FORESTER.—The simplest test of the fitness of water for photographic purposes is to add a few grains of nitrate of silver, and place it in the light. If it contain chlorides or carbonates, a white precipitate will be formed at once. If organic matter, it will discolour in the light.

BROMO.—We do not know anything of the chemical constitution of Judson's dyes, but should not think them safe for repeating the experiments described by Captain Abney. We do not know where the substances named can be obtained certainly, but probably of a manufacturing chemist's house, like that of Hopkin and Williamis.

J. C. G.—The process of enamelling cards could not be described in the space we can devote to answering correspondents. Our correspondent cannot have been in the habit of reading his *News* with any attention, as we have described the process in detail repeatedly in past issues. You will find an article on the subject in our *YEAR-BOOK* for 1878.

OPERATOR.—We have recently repeated several times formulæ for developing collodion transfer pictures. Take the following, which will answer well:—Pyrogallie acid, 2 grains; citric acid, 1 grain; acetic acid, 30 minims; water, 1 ounce. We fear that you will find it very difficult to use bromide in the developer with such a process. The alkaline pyro is only suitable for bromide plates. We have tried a bromide in the developer in the wet process, but without satisfactory results.

Several correspondents in our next.

PATENTS.

BY F. DES VREUX,

Patent, Trade Marks, and Designs Agent, 32, Southampton Buildings, W. C.

Provisional Protection for six months has been granted to:—
1183. James B. Spurge, Analytical Chymist, and John Whitcher, Photographer, both of South Street, Romford, Essex, for the invention of "Improvements in or applicable to apparatus for covering or exposing the lenses of photographic apparatus."

Notice to proceed has been given by:—
5036. Theodore Pixis, of Munich, in the Kingdom of Bavaria, in respect of the invention of "Improvements in the mode of transferring photographic pictures."

The Photographic News, April 25, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHERS VERSUS PAINTERS IN THE MATTER OF COPYRIGHT—ARTIFICIAL LIGHT—COMMERCIAL DRY PLATES ABROAD—BALLOON AND CAMERA IN NATAL.

Photographers versus Painters in the Matter of Copyright.—The copyright action which was decided at Maidstone last week will go a good way to strengthen the rights of photographers to their own work. We have had several amusing letters—to use a mild expression—in these columns anent copyright in photographs, in which those who have pirated work, when called upon to explain their conduct, have replied with singularly ingenious and artless expressions. One of the last examples was that pointed out by Mr. H. P. Robinson, of Tunbridge Wells, in which case the offender was the editor of a religious journal. We do not know if "On the Look Out," one of the most striking pictures, two or three years ago, at Pall Mall—an old fisherman, looking over a wall, with short pipe and sou'wester—has been reproduced by leave of the photographer, but, if not, we should advise his calling to account the publishers of a coloured almanac that is to be seen everywhere, and upon which the well-known figure-head appears as large as life, or, rather, as large as the original. The Maidstone case is exactly parallel to another one in which Mr. Robinson was also the complainant, and in which, it may be remembered, a painter copied one of Mr. Robinson's photographs, the painter in question naively remarking that he had seen the photograph at the house of a friend, and thought there was no harm in copying it. In the Maidstone case the injured photographer, unlike Mr. Robinson, took the matter into Court for decision, and at once gained his action. A London painter, one Mr. Hills, produced a picture of Old Maidstone Bridge, a picturesque structure spanning the Medway, which doubtless many of our readers remember. There was no reason at all why he should not depict such a fine bit of antiquity. Indeed, old Maidstone Bridge, with the quaint church and ivied walls down by the placid river, the trim College grounds and the green meadow slope that borders the brimming water, together make up a nook that artists have time after time depicted. But Mr. Hills, instead of taking his canvas to the river bank, selecting his sites, and composing his picture on the spot, had recourse to the work of a Maidstone photographer who had done all these preliminaries. His oil painting was, indeed, but the transcript of a photograph: there was plenty of original work, no doubt, in his finished picture, but, unfortunately, it included likewise all the points of the photographer's work as well. There could be no question about this, and the result was, as we say, that the County Court judge pronounced in favour of the plaintiff. The judge ordered Mr. Hills to pay the penalty of a guinea, and to make over his picture to the plaintiff, the picture being valued at thirty guineas. We are glad to see that the photographer's sense of justice was equalled by his generosity, for he declined to accept the painting for himself, suggesting that it should be given to the Maidstone Museum; and this course was in the end adopted.

Artificial Lighting.—The question of photographing by artificial light is attracting attention in Berlin almost as much as in this country; and Herr Duby recently gave a lecture on the subject before the Berlin Photographic Society. One hint should not be lost upon those who are attempting the use of ordinary gas, which, as correspondents in our pages have shown, seems to give most promising results. The hint we refer to reminds those who employ gas how much they can at any time magnify the lighting power by employing in the tube through

which the gas passes some loose cotton wool impregnated with naphtha, benzine, or carburetted liquids. An arrangement, indeed, may be effected whereby the coal gas can be allowed to bubble through a liquid of the kind we have mentioned, and in this way a jet of constant power can be secured of an intense character through the medium of an ordinary burner. The most simple arrangement is to put a piece of flexible tubing upon a gas bracket, then connect a piece of glass tubing in which the wet cotton wool is, or the bubbling apparatus, and then by means of another piece of flexible tubing connect the burner. If the cotton-wool arrangement is made use of, an arrangement is then at hand whereby this is easily replenished, and a change may be effected at every exposure, if need be, without the least difficulty. The improved Sugg burner, something of the character of the brilliant lamps which are to be found just now in Waterloo Place and in Queen Victoria Street, also furnishes a very dazzling light, and this by merely burning the gas in an improved manner, without any aid from a carburetted liquid.

Commercial Dry Plates Abroad.—The matter of commercial dry plates seems to have attracted the attention of the Vienna Photographic Society, and some of the members have expressed regrets that there are no makers of these requisites in South Germany. "In England," said one of the members, "there appeared to be a great traffic in dry plates, probably in consequence of the large number of amateurs who pursue photography as an amusement." We gave the same explanation a short time back in these columns, and cited the large amateur element in this country as one of the reasons why Great Britain has been to the fore in improvements connected with dry plates. But the Viennese are not to be beaten, and so it appears that, since no firm in Austria will prepare sensitive films for sale, supplies are to be drawn from London houses. There is, however, a difficulty in the way in the form of Custom Houses, which desire to search packages before they can be permitted to pass, and unless, therefore, the Custom restrictions can be modified, these supplies will be few and far between. This circumstance, we remember, caused a great deal of anxiety on the part of one of our correspondents some years ago, who desired to pass a packet of dry plates through the Copenhagen Customs. In this case the officers wanted to open the packages, and would not permit the plates to pass without inspection. Fortunately for our friend, they had been put up in parcels of four only, and the officials at last were satisfied that it was but a question of glass plates when the small individual packages were placed before them. Whether the German and Austrian Customs are as strict, we do not know.

Balloon and Camera in Natal.—There seems little doubt that a balloon equipment will be sent out to the Cape for reconnaissance purposes, and a camera will in all probability form part of the aeronaut's equipment. The equipment is to be of such a nature as to be able to provide the gas necessary for inflating the balloon, and this gas is to be hydrogen. A portable furnace will be carried, having tubes in the interior filled with iron. A small boiler provides a supply of steam; this steam is passed through the heated tubes, and the iron in these tubes, becoming rusted by absorbing the oxygen from the steam, the hydrogen is allowed to pass out and fill the balloon. The hydrogen would, under ordinary circumstances, be rather wet, and therefore a desiccating arrangement of some kind will have to be provided. So far, we believe, the army under Lord Chelmsford is unprovided with photographic apparatus, a matter all the more to be deplored, since, if the camera can serve for nothing else, it can provide illustrations for the General's report to the Commander-in-Chief. But if a balloon is sent, a camera will be well-nigh indispensable, for it can see quicker and better than the human eye; and, moreover, make record of what it does see.

GELATINE PLATES IN INDIA.

BY COL. F. DAWSON.

DURING the past twelve months I have experimented upon gelatine plates and pellicle, and thinking my notes may be of use to others, I take the liberty of jotting them down.

It is quite possible to develop plates with the liquids used at the temperature of 85° Fah.

It is quite easy to make your own dry pellicle without setting the jelly or using ice.

To Make Pellicle.

Nelson's gelatine	250 grains
Brom. potassium	200 "
Distilled water	5 ounces

Use pounded and dried bromide, weigh carefully, and dissolve in 4 ounces of the water; now weigh the gelatine, and place in a yellow hock bottle; filter the bromide into the bottle, and wash out the filter with the remaining ounce of water.

Allow the gelatine to soak for two hours, when it should be quite swollen and soft. Now have a large saucepan full of nearly boiling water, dip the bottle into the hot water quickly for a second, continue the dipping until there is no fear of the bottle breaking and it becomes as hot as the water, shake up, and ascertain that the gelatine is quite dissolved.

Melt 280 grains fused nitrate of silver in 2 ounces of distilled water, filter, and wash out the filter with 1 ounce of distilled water. Place this clear solution in a small bottle in the hot water until warm.

Now add the silver solution to the gelatine in small quantities, not exceeding 10 minims at a time, with violent shaking after each addition; when the whole of the silver is added, shake up for five minutes, and place the bottle in the hot water; give occasional shaking at intervals of a quarter of an hour for two hours, then leave the bottle in the hot water for at least four hours longer (occasional shaking is an advantage); at the end of these six hours the water will have cooled to 85° or 90° Fah., about the temperature of the atmosphere.

Now remove the bottle, and into it pour, by an ounce at a time,—

Methylated absolute alcohol	...	6 ounces
Methylated spirit	...	6 "
(The spirits must be free from gum.)		

Shake up violently after each addition of the spirits, and continue adding at intervals of a few minutes, until the gelatine begins to precipitate upon the sides of the bottle; when this is observed, add an extra ounce or two, according to available space in the bottle, shake up violently, and leave standing in the dark room for two or more hours. One hour may be found to be sufficient; the appearance of the fluid in the bottle should be your guide.

If, upon pouring a small quantity into a minim measure, it appears thick and very milky, either sufficient time has not elapsed, or your spirits are too weak, or you have not used enough. As a rule, two ounces of the mixed spirits are enough to abstract 1 ounce of water known to be used in the formula.

If the liquid in the minim measure is merely opalescent, you may with confidence pour out the whole of the fluid. If, after the fluid has stood for two hours, the gelatine has not separated, you have made some mistake.

When the pellicle has precipitated, pour off the fluid and drain the bottle; now pour into the bottle 2 ounces distilled water, place in hot water and re-melt the gelatine, pour out as much as possible into a clean glass dish, and remove the surplus adhering to the bottle by additions of 1 ounce distilled water at a time; 2 separate ounces I find quite sufficient. With a glass rod mix the gelatine in the dish, and then with one hand stir up, and with the other slowly pour

in 2 ounces of spirit (same strength as before) for every 1 ounce of water you have used in re-dissolving the pellicle.

Almost immediately the gelatine will stick to the glass rod, and also to the bottom of the dish; continue stirring until the whole of the pellicle is collected in a lump on the glass and a part smeared over the dish, but with the spirit only slightly opalescent; when this is the case throw off the spirit and drain the dish, then pour into the dish an ounce or two absolute alcohol, and knead with your fingers the pulpy mass of gelatine; scrape up all you can from the dish with an ivory knife; after a few minutes you will find the gelatine getting tougher and tougher; pull it into bits and keep it well wetted with spirit; it will not adhere to the fingers. When the pellicle becomes about as tough as a piece of india-rubber of similar size, drain the dish; give the pellicle a squeeze in a clean pocket handkerchief or towel, and proceed to tear it into very small bits; now place the dish containing the bits on a tin dish of hot water or other means of applying heat by water. As time passes inspect your pellicle; you will find the outside gets hard, while the inside remains soft; when this is the case, tear the bits into smaller bits, and continue the drying and tearing until the pellicle is as dry as it is possible to make it. Then place it in a stoppered bottle and keep in the dark.

The fused nitrate of silver is simply crystalized silver brought to melting in a small capsule.

I have used pure spirits with similar results. Crystalized silver may be used without fusing.

For Use.

Dry pellicle	2 drachms
Distilled water	3 ounces
Spirits of wine	1 drachm

Allow the above to soak for a couple of hours in a 6-ounce stoppered bottle, then warm in a mug of hot water; shake up well until the ingredients are thoroughly incorporated, and filter.

The above quantity will coat 18 plates 8 by 5.

To Prepare the Plates.—Obtain a 2-ounce glass filter round the nose tie muslin four thicknesses, and clip.

Next obtain a 4-ounce comestible collodion pourer. Remove the pourer, and into it plug a thin piece of sponge, sufficiently thin to permit the gelatine to flow through it and stop bubbles.

Damp the sponge before use. Filter the gelatine into the collodion bottle, and replace the pourer. Place the filter in the stock bottle, and stand it in a tin pot of hot water. In another tin pot of hot water stand the collodion-pourer containing the gelatine. Have ready some pieces of plate glass carefully levelled on a table and capable of holding 18 plates 8 by 5; also have ready some means of warming the plates—a spirit lamp or a tin water bath. Warm each plate sufficiently, about as warm as you would when varnishing a negative, rather under than over. Now pour the gelatine on to the plate exactly as you would collodion, let it run all over the plate, and then pour off into the filter, while you count three in quick time.

Remove any surplus from the corner or back of the plate by passing the finger over the spot, and at once place the plate down on the levelled plate glass. The plates will take about one hour to prepare, and will be perfectly dry in four hours; some, of course, will be dry before others. The candle may with impunity be nine feet from the place you are preparing the plates. Plates prepared by the above formula are at least as sensitive as wet collodion, and I find no signs of fogging from the candlelight. The colour of the film is a deep ruby. The films should be fairly thick, but not too thick. If, in using the amount here named, you can prepare 18 plates 8 by 5, you may anticipate they are correct. If the plates are much longer in drying than four hours, you may conclude they are too thick, especially if you have not one dozen and a half.

One drachm of alcohol is quite enough for three ounces of

water; more has a tendency (as pointed out to me by Mr. Kennett) to drive the gelatine too much towards the edge of the plate, and I also find that much more than one drachm causes the film to dry in waves of unequal thickness, with a watered-silk like appearance on the surface.

The plates must be perfectly dry before placing in plate-box or holder. I have not found backing of the least good in preventing blurring. If the subject is carefully selected, and the films are fairly thick, I do not find any tendency to blurring. If the gelatine is poured on to the glass in sufficient quantity, it will run like collodion. If you do not pour on enough gelatine, the chances are it will not run all over the plate, but have a desire to go its own way; in this case *freely use the finger* to guide it, but be careful not to place the finger on and touching the glass; keep the finger in the gelatine, and on all occasions of using the finger be careful not to remove it from the gelatine until you have brought it to the edge of the plate and towards that side whence you intend to pour off. Bubbles are most difficult to see and remove: be careful to avoid making them.

Holding the plate after coating for any time will result in the gelatine being repelled in the neighbourhood of the fingers.

To Expose and Develop.—I find that success mainly depends on correct exposure. Where there are great contrasts from very bright light, you must give a longer exposure than when the picture is not so brightly lighted, otherwise you will have chalky whites and black shadows. A good negative is a very poor thing to look at in point of density. If it is in appearance approaching the density of even a weak collodion negative it is useless; it should have the appearance of a greenish looking transparency. The time of exposure may be for ordinary landscapes from three to fifteen seconds. I have not myself succeeded with long exposures, except when using Kennett's slow plates; these will stand many minutes' exposure, and without a sign of blurring.

Development.—Place the exposed plate in a dish, and dash over its surface two ounces of filtered pyrogallic, 4 grains to 1 ounce of distilled water, into the glass. Measure, pour 2 drams of the following,

Brom. potassium	23 grains
Liq. ammonia fort.	30 mins.
Distilled water	2 ounces

Pour off the pyro on to this mixture in the measure, and as quickly as possible pour on to the plate in the dish. The image starts out at once, and in five to ten seconds the development is complete. The appearance of the negative at this stage is very deceptive: it should *not look fogged*, but with this exception very little idea of what the negative will be is obtained. Have ready your hypo, one ounce dissolved in four ounces common water. Pour off your pyro developer, and at once pour on the hypo, being careful not to pour it on to the plate, but pouring freely and flooding it over quickly. Be careful to keep the plate in the dark until perfectly fixed, or there will be stains. It is quite impossible to fix a negative without stains if it be taken to the light before fixing.

The secret of being able to work with all the solutions at upwards of 80° depends upon having everything ready and working quickly. Immediately the negative is perfectly fixed, remove it, and, holding it by the corners, place downwards. Place it in a basin of water as cold as you can procure it, move it very gently for about ten seconds, change the water, again wash for ten seconds, and leave up on a corner to dry.

If care has been used, there will be no frilling or blistering, and the negative will be dry in half an hour or so in the open air—not, of course, in the sun. I have tried using spirits to draw out the water before the plate is reared up to dry. I have not been successful; unless the spirits of wine be very cold (artificially cold), the image seems to be raised in relief by the action of the spirit upon the film.

I have never varnished a negative; it may be necessary in a climate where the air is charged with moisture, but I have no experience with such a climate.

Kennett's pellicle is better in every way than what I make, but when you have not a stock of Kennett, it is as well to know how to manage, however indifferently, without it. With a packet of Kennett's sensitized pellicle, and 340 grains Liverpool dry collodion pellicle, I would go anywhere and undertake to take any description of landscape I have met in India.

In conclusion, I beg to assure you that I do not wish it to be understood that I recommend the above preparations to the detriment of other manufacturers, but simply because I have extended experience with them, and none whatever with any other.

The amount of pellicle resulting from the formula I have given, allowing for waste, &c., should be enough to coat at least six dozen plates 8 by 5.

Secunderabad, 27th March.

ON SOME EXPERIENCES WITH GELATINE EMULSION.

BY HERBERT B. BERKELEY.*

THE rage for gelatine emulsion is certainly on us again. This process is especially interesting at this season of the year, when processes are tried, but not thoroughly tested. Let us hope that *this* time certain mechanical difficulties, hitherto so closely connected with this process, have been got over.

As gelatine emulsion has been "looking up," I also have been looking up gelatine emulsion, at least so far as my notebook has allowed, and it has struck me that some of these notes, if put in a comprehensive form, might prove of interest to the members of this Society.

In my opinion an alcoholic emulsion will probably be found to conduce to good keeping properties, and therefore to mechanical excellence. For this purpose, however, a suitable gelatine must be chosen, as failure is inevitable with certain kinds.

I hand round a plate that was coated with an alcoholic emulsion. It will be seen that the alcohol has repelled the more watery solution of gelatine, due to more rapid evaporation at the edges.

At a former period I advocated the use of free silver nitrate in the preparation of the emulsion; and I believe now, after all that has been written against it, that plates prepared in this way are more easily developed than when soluble bromide in excess is used. Red fog may arise, but not necessarily. There is some difficulty in dissolving gelatine prepared with excess of silver nitrate in water containing any large proportion of alcohol. It was found necessary to make the emulsion with soluble bromide in excess, to wash, and then dissolve in water and alcohol, equal parts. The addition of a trace of silver nitrate now causes a precipitation, sometimes of both gelatine and bromide. If a plate be coated with the emulsion in this state the effect, at best, is as shown by the plate I now pass round. (It has become darkened by exposure to light, but the granular effect may be seen.) The emulsion may be allowed to digest, and, on adding sufficient soluble bromide to convert the silver nitrate, complete emulsification takes place again. This action appears to me very peculiar and interesting. If an emulsion be prepared with free silver nitrate before attempting to dissolve it in dilute alcohol, solution does not take place properly, even though free bromide be afterwards added. This applies, however, to ammonium bromide emulsion; when zinc bromide is used with free nitrate, solution readily takes place, but even plates cannot be obtained with the opaque gelatine. With alcoholic emulsion excess of silver nitrate causes curious vagaries. An emulsion may be prepared with ammonium

* Read before the Photographic Society of Great Britain.

bromide and excess of silver, even when as much as forty grains of opaque gelatine are used to the ounce of methylated spirit and water, equal parts. But when the same emulsion has been washed, and diluted with water to half the former strength, it is not possible to use more than somewhat under a quarter bulk of spirit. It seems as if the gelatine, having once experienced the blessing of pure water would not again take readily to "spirits."

An alcoholic solution of gelatine, in which is ammonium bromide, on cooling, remains semi-opaque; while an alcoholic solution with zinc bromide becomes milk white. The "No. 1" gelatine may differ from the opaque in many respects.

I cannot, in view of what we hear at the present time of the sensitiveness of gelatine plates prepared with excess of soluble bromide, press the use of free silver nitrate. I am, however, confident that greater latitude of exposure is possible with plates prepared by the latter plan. At the same time they do not appear to keep well; of this there have been several instances.

Red fog, when it is met with in plates which were formerly free from it, seems to destroy all sensitiveness; plates which are afflicted with the fog at the time of preparation retain their sensitiveness; the fog in this case does not prevent the development of an image.

Restraining acid is not necessary with either gelatine or gum-arabic emulsion with excess of silver. Cannot fog in collodion emulsion be caused by a combination of silver with an organic substance? Emulsion made with gum-arabic and kept with excess of silver for a week gave cleaner plates and less detail than the same emulsion kept with the excess during eighteen hours only. Can any one crack that "nut" for me?

I find there is a note to the effect that plates which have been kept dry rapidly after development. Again, that plates which have been carefully kept are less subject to blisters than freshly-prepared plates, perhaps through the film becoming more insoluble. There is certainly a change produced by keeping gelatine plates: they become less absorbent.

It has struck me that the "No. 2" gelatine might give a harder film, and one less liable to blister.

On one occasion I had a curious experience. Two gelatine emulsions were prepared with zinc bromide; their composition was alike, except that one contained an alcoholic decoction of pyroxylin. I will dismiss the decoction with the remark that the tones obtained were blacker and more vigorous; perhaps there was a little more detail visible. But what I want to notice is this: both emulsions being prepared with one grain of silver nitrate in excess, and having been kept warm for an hour and a half, were washed, and plates were made from the resulting emulsions. These were very transparent, and proved about one-fourth as sensitive as zinc collodion emulsion. They were, therefore, decidedly slow. The emulsions were allowed to set in the bottles, and then a little ether was poured on the surface of each; in this way they were kept for several days. At the end of this time I was surprised to find that both the emulsions had become more opaque, though it should be noted that they were not kept in the fluid condition. On preparing plates, the sensitiveness was found to be increased fourfold; they were now as sensitive as the zinc collodion—indeed, instead of being slow, they had become rather rapid.

What was the cause of this unusual change? It could not be reproduced, though the effect of ether was tried, and also that of a trace of free silver nitrate (thinking it possible that a trace of nitrate might have escaped detection after washing); but the silver nitrate had exactly the opposite effect, for, after the lapse of several days, it rather diminished the sensitiveness, and gave additional clearness.

In the previous case, to which I have just referred, the ripening of the emulsion appears to have proceeded while the

latter was in the *solidified* condition. As the emulsion had been washed, the bromide must have entered into another mechanical state, and perhaps reacted with the gelatine; and all this in the absence of any other body.

HOW TO TAKE A NEGATIVE BY ARTIFICIAL LIGHT FOR THREE-HALF PENCE.

BY A. BRITTLEBANK.*

THE subject upon which I am about to say a few words this evening seems to be attracting the attention of many photographers, and will, I have no doubt, prove a new source of income to many of us who persevere in this branch of the art. I allude to the different means which have lately been adopted in order to produce satisfactory portraits without the aid of daylight. Electric light, parabolic reflectors, and Fresnel lenses, pyrotechnic compounds, and other more or less expensive and dangerous appliances seem to be forcing themselves on our notice, and each device has, no doubt, cost its promoters a considerable number of vexatious and troublesome experiments before it has been brought to its present state of efficiency.

I do not wish it to be thought that I have any desire in the present communication to detract anything whatever from the credit and merit due to those gentlemen who have preceded me in this special branch, and who have really made a great stride in science. They have undoubtedly demonstrated the possibility of producing satisfactory portraits without daylight, but each of the systems has its own peculiar drawbacks. The electric light will, no doubt, be able to hold its own against all other sources of illumination; but the costly plant must prove a serious obstacle to a great number of persons. The luxograph, though not so expensive, is not suitable for many purposes to which artificial light might be profitably applied, mainly on account of the cumbersome and unwieldy reflector at present employed, and the trouble of getting rid of the products of combustion without a structural alteration of the room in which it is employed; and this is a serious consideration if the apparatus is only to be used, perhaps, once in the same room.

I consider for this class of work all the apparatus necessary ought to be so portable as to be carried in a cab at an hour's notice, so that it may be no uncommon thing for Mr. Photographer to be requested to attend on the Hon. So-and-So to take twenty or thirty negatives to-morrow night; and I shall endeavour to show how this can be accomplished by anyone without putting himself at all out of the way, with the outlay of a few pounds only in apparatus, and with an expenditure of about twopennyworth of light for each negative taken.

I will first say a few words about the parabolic reflector as at present in use, the form of which is not suitable for the work to be done, and is, moreover, not the most economical shape to illuminate the object to be photographed. A circular reflector will project a circle of light on the background provided it is at right angles to it, and, consequently, all the light which impinges on the background outside of the oblong figure to be cut out of it is wasted, as will be seen in the diagram (*fig. 1*), and really ought to be utilised by only illuminating the actually required portion. This I know cannot be positively done in practice, as it is the natural tendency of light to radiate in all directions; but I think it is sufficiently plain to everyone that we ought to use a reflector of a rectangular form for rectangular or oblong work. This form is, moreover, much simpler in construction, as it is only necessary to bend tin or silvered copper plates to the parabolic curve in one direction in order to form a rectangular reflector whose sides are parabolic.

But if we go a little further into the case by examining what a parabolic curve really is, I think it can be shown that we can do without it altogether. The curve parabola

* Read before the South London Photographic Society.

is, as most of you are doubtless aware, the section of a cone parallel to one of its sides (fig. 2), and is theoretically the

Fig. 1.

Fig. 2.

most suitable curve for reflecting nearly parallel rays. It is likewise called the curve of equal strength, and is the form used for large girders for building purposes. One of the simplest means of constructing this curve, after having determined its height and breadth, is to draw a rectangular figure, as A B C D (fig. 3), divide the base A B into two

Fig. 3.

equal parts, and erect a perpendicular on the point E F. Divide the line A E into any number of equal parts (say four), and draw lines parallel to E F; next divide the line A D also into four equal parts, and draw lines from F to the points at which A D is divided. If we now describe a curve passing through the points where the lines last drawn intersect the perpendiculars, we shall have a parabolic curve. But, as will be seen in diagram (fig. 4), if, instead of cutting

Fig. 4.

the cone near its base, we take a long slice off near its apex, we get a different shaped curve altogether, the lower portion so nearly approaching a straight line that, for all practical purposes, we might as well have straight sides to the reflector, as will be presently shown by actual experiment.

The reflector which I am about to use is made of tin and supported on three legs, which can be detached from it when not in use, and any required angle can be given to it by lengthening or shortening the legs, as in many tripod stands. In front of the reflector is placed a diffuser, which may be made of ground glass, tracing-paper, or other semi-trans-

parent medium, to soften the intensity of the light transmitted through it, in the same manner as the windows of our studios are treated where the direct rays from the sun are likely to fall on the subject to be photographed.

A side screen must be used to reflect light on to the shadow side, and should consist of two light frames covered with calico or white paper, and hinged so that they can be folded together when not in use, and when open be capable of standing without other support.

Lastly, we come to the light itself. This may be readily explained by the rough model which I now exhibit, and which I have purposely left in its primitive state in order to show what kind of results can be obtained by these simple and inexpensive appliances. The lamp consists of about twenty or more small tubes of brass, clamped together between two pieces of wood, and secured in the frame in front of two rollers covered with india-rubber, through which the strands of magnesium ribbon are made to pass. At the back of the rollers is a guide plate to keep the ribbons in proper position; then, by turning the wheel, the ribbon can be advanced as fast as it is consumed, or a certain portion may be wound out and lighted in the gas flame and allowed to burn out. Thus it will be seen that by this extremely simple device we are enabled to get an exact quantity of light, and having once determined the exposure necessary, but little judgment is afterwards required.

The magnesium ribbon burns at the rate of about six inches in twenty seconds, and I find that the combustion of twenty inches is sufficient to produce the negatives which I offer for your inspection with the accompanying prints. They are the first negatives which have ever been taken with the lamp, and the exposures were from five to eight seconds. The present cost of magnesium is 10s. per ounce, which contains about sixty yards, equal to about 2d. per yard; thus the exposure costs (say) three-halfpence for each negative. The very small quantity of smoke generated by combustion need hardly be taken into consideration when only a few negatives are required. Another point which must commend itself to everyone interested is the entire absence of danger, and the cleanliness of magnesium ribbon.

I will now make a few remarks respecting illumination. In the present advanced state of photography, and considering the generally fairly-executed work the public are accustomed to see, it is absolutely necessary for the successful employment of these supplementary appliances that the work produced by their aid should equal that made in daylight. In consequence of the simple and inexpensive nature of my lighting apparatus it is possible to employ two or more lamps for our purpose in order to produce any desired effect of light and shade. Thus, a fifteen or twenty-light lamp may be used to light the principal part of the figure, and a five-light lamp for the shadow side; by this means reflecting screens can be done away with, and the whole of the arrangements may be controlled by one person. To effect this object I propose to wind out the desired length of magnesium ribbon in each lamp, and, having previously connected the gas supply for each lamp to one stopcock, all that remains for the operator to do is to light the gas-burners low, and when ready for exposure, turn the gas on to the full, which will light the magnesium, and at once uncap the lens and make the exposure.

I believe by a modification of this system, and by using a sufficient number of lamps, it is not only possible to take single figures, but groups of persons with the same ease and facility. The brilliancy of the light will not cause any inconvenience to the sitter, provided he does not look directly at the light.

In conclusion: I have to remark that the negatives shown are taken with Messrs. Wratten and Wainwright's dry plates (exposure five and eight seconds), and were developed by Mr. Cobb, who has kindly consented to assist me this evening in conjunction with Mr. Cowan. I have only now to add that anyone is perfectly at liberty to use or improve on the system I have just described.

SHARP DEFINITION IN PORTRAITS.

THE recent press notices of the death of a distinguished lady and enthusiastic photographer recall the memories of a discussion which waxed hot something like a dozen years ago. The bone of contention was whether extreme sharpness, or haziness of outline, was desirable in photographic portraiture. The aim amongst photographers generally was to secure the most perfect definition—the greatest sharpness possible—in their portraits, and in criticizing a photograph they would examine with a powerful lens, and if every single hair could be separated and counted, it was pronounced good; if not, it was wanting. Some of the most artistic and cultivated photographers, however, have always avoided the cutting hardness in question, aiming at softness and modelling, with just sufficient definition to avoid fuzziness. Many had done this with such moderation and judgment that, whilst the charming delicacy and artistic grace were recognized, the want of sharpness did not challenge attention. The exhibition of a large number of the portraits produced by Mrs. Cameron very definitely raised the issue as to whether almost entire disregard of definition was legitimate in photography. The portraits in question were, in many respects, very remarkable ones. They were in many instances likenesses of distinguished persons, and in not a few cases they were produced from grand models. The pictures were, moreover, whatever might be wanting in technical points, generally distinguished by artistic feeling. There was a massive treatment, and a feeling of breadth which was very effective. The effect of light and shade was bold and forcible; and the general effect was distinctly a novelty in photography. Artists who had rebelled against the crisp, hard, sharp, map-like delineations too commonly produced by many photographers, accepted the daringly rough, not to say slovenly, sketchy sun-pictures, so unlike all photographs hitherto produced, as the discovery of a grand possibility in photography. At any rate, it was possible to admire these without any sacrifice of *amour propre*. Photographs with fine definition and detail and true drawing had often been a reproach to the slovenly slap-dash painter, content to get effects, without precision of detail and accuracy of drawing. These new photographs had much of the charm of skilful artists' unfinished sketch from nature—rough, suggestive, and lacking detail, but fresh and effective. Some few distinguished artists and art critics, and many art pretenders, admired these pictures, and affected to find in them a revelation; whilst almost all capable photographers, and many art connoisseurs, including Professor Ruskin, altogether condemned them. The most distinguished art photographers, as typified by Mr. H. P. Robinson, failed to see anything in them which photographers might with advantage follow

—anything which added to the genuinely pictorial quality of photographs—believing that neat manipulation and reasonably precise definition, were not inimical to art truth. Excessive sharpness in unimportant details had been condemned and avoided by the best photographers from the earliest days of the art, and various methods, generally of a mechanical kind, had been devised to secure softness, in place of hard sharp cutting definition. Printing through a medium, moving the focus of the lens during exposure, printing from two similar negatives, and some other plans were proposed and tried; but none came into general practice. The most prevalent means of modifying results was probably the use of lenses made especially to give a more diffused definition in place of cutting sharpness or on plane.

Amongst the most efficient methods of late years, the method of using reproduced negatives with double retouching appears to be well worthy of attention. A transparency from the original negative admits of one kind of retouching. The sharp, black touches required in the finished print are easily put into the transparency. To take an illustration. It is said that Sir Thomas Lawrence, as a rule, left the features generally lacking in sharp definition, a soft and almost fuzzy style of delineation being employed; the eyes and the lines about them were, however, sharp and crisply defined. This gave force and intelligence to the expression, and a look of character to the most common-place face. This effect is easily produced by touching in the transparency. Even if the faces generally appear sadly wanting in definition, the picture will seem sharp enough if the eyes are sharp, which may be effected by a few crisp touches on the transparency. Soft, even fuzzy, definition will generally be tolerated where it removes the effect of scars, poek marks, freckles, and rugose texture of skin; but the lack-lustre eye, which is the consequence of imperfect definition, is generally offensive. For ordinary work, the every-day practice of photography, the skilful worker will get good results by means of ordinary appliances; but where difficult faces have to be dealt with, and especially where a sufficiently large number of prints are required to justify reproduction and multiplication of negatives, the system of double retouching in giving artistic and pleasing qualities to the portrait is one well worth consideration.

A NEW SOLVENT OF PYROXYLINE.

BY H. BADEN PRITCHARD, F.C.S.,

Of the General Photographic Establishment of the War Department.

M. NOBEL, the eminent Swedish engineer, to whom is due the honour of having developed the useful qualities of nitro-glycerine, and applied this valuable blasting agent in the form of dynamite and similar compounds to warlike and industrial purposes, has lately discovered a further quality in the substance. Nitro-glycerine, which is obtained by allowing glycerine to fall drop by drop into strong nitric acid, and thus effecting the nitrification of the glycerine, may be looked upon to all intents and purposes as a liquid gun-cotton, the composition, action, and mode of detonation being similar.

M. Nobel has now brought forward another explosive compound, more violent in its action than gun-cotton or any of the nitro-glycerine preparations hitherto known. He calls it blasting gelatine, but it is gelatine only in appearance, and has none of that material in its composition. The blasting gelatine is, in fact, simply a combination of nitro-glycerine and gun-cotton. M. Nobel does not take the highly explosive cotton—tri-nitro-cellulose—but the less explosive, or collodion pyroxyline, and this he finds is something more soluble in nitro-glycerine than it is in alcohol and ether. Indeed, from seven to ten per cent. of photographer's pyroxyline may be dissolved in nitro-glycerine, the product being, as I have said, a harmonious gelatine mass that is very highly explosive.

I have made some experiments with this new description of collodion, if the name may be given to it. My sample contained seven per cent. of pyroxyline, and this was iodized with the same solution as that employed for Mawson's collodion. The film, when applied to the glass plate, had more the appearance of thick gum-water than collodion, and was not perfectly set—as well prepared blasting gelatine should be—when put into the silver bath. The result was but an image of the faintest kind after prolonged exposure in a strong light, and, moreover, the picture appeared but on the surface, and not in the film itself, as in the case of an ordinary negative. Repeated experiments did not give more hopeful results, and it was very apparent that the new solvent of pyroxyline has little value to the photographer as furnishing a vehicle for silver salts. To those who desire to experiment further with the compound, I would mention that it is of a very poisonous character, and the mere toning of the film, to see if it has set, with the fingers, is likely to bring about a severe headache. This circumstance should be borne in mind by all who have to do with nitro-glycerine preparations.

But if blasting gelatine is unlikely to find employment in photography, it bids fair to elbow itself to the front for military and engineering purposes. Already, as I have said, its action has proved to be more violent than gun-cotton or dynamite, and recently, since Professor Abel's experiments, a further stride seems possible. That chemist has prepared a more novel explosive still by adding to the gelatinous mass a further quantity of gun-cotton, but this time not photographer's pyroxyline, but the highly explosive trinitro-cellulose. The addition of the latter makes the mass into a kind of white dough, which is more easy to handle than the "gelatine," and which has still more destructive properties; so that the last solvent of pyroxyline is likely to play an important rôle in the future.

FRENCH CORRESPONDENCE.

GELATINO-BROMIDE PROCESS—M. BARDY AND THE CHROMOGRAPH—AWARD OF THE PRIZE FOR THE BEST TRAVELLING CAMERA—LECTURE ON THE APPLICATIONS ON PHOTOGRAPHY TO THE INDUSTRIAL ARTS—CONGRESS OF PROVINCIAL LEARNED SOCIETIES AT THE SORBONNE.

The Gelatino-Bromide Process.—As the remarks made at the last meeting of the Photographic Society of France, held on the 4th April, go to prove, the question of the gelatino-bromide process for the production of negatives threatens to be in this country the main point which will occupy the attention of all the true friends of the progress of photography. In England the subject has not so recently come into notice, and the productions of Mr. Kennett have already for some time enabled us to recognize the great part which the process is capable of playing—a process which not only possesses extraordinary rapidity, but by aid of which also we can prepare for any length of time in advance, and in any desired quantity, sensitive films remarkable for their permanence. With us in France, another path was at first struck out; it seemed as if the philosopher's stone of camera printing would be found in the emulsion process—in my own humble opinion a process too delicate, and requiring too complicated a development, to ever realise the desideratum that had been sought for. It is quite otherwise with gelatino-bromide plates, whose extraordinary rapidity and easy development recommend them strongly for use, not only in the studio, but also in all out-door work. This problem—the production of a sensitive film which shall be capable of working in a dry state and with great celerity—has long been studied, and its complete solution is now before us. Here, then, is a new road open to industrial and scientific workers, of such a kind that each one, while pursuing his own speciality, will be able to make use of what we may call the *photographic pencil* for illustrating his ideas, after a very short apprentice-

ship in the manner of using it. The greater the improvements introduced into such work, the more will the applications of photography be promoted. As an illustration of what I would imply, I may point to the art of printing by means of zinc plates, which only became widely extended after a few special establishments had used every exertion to produce photographic wood-cuts. Now the same thing will happen with photographic negatives as soon as we can procure commercially sensitive films ready for use, just as we can purchase cartridges for charging our guns or pistols. For as a time will come—and that a not very distant one—when every one will receive, as part of liberal education, a special instruction in the use of a photographic apparatus, we shall each of us carry about this instrument in our portmanteaus, and no one will travel without bringing away with him photographic recollections of his excursions. These ideas are suggested to me by the high state of perfection to which the gelatino-bromide process has been brought. Up to the present time we have had plenty of different kinds of dry plates to take with us on our travels, but the long exposure required, and the uncertainty of the results, were enough to discourage not only those who used these plates, but still more those who were desirous of working with them, provided the manipulations were easy and the results constant. Very soon, now, manufacturing establishments for the production of plates and pellicles of gelatino-bromide will be opened. Portable apparatus, like that which is so well made in England—much better than with us—will be produced in any quantity, to realise the idea of what I have called the *photographic pencil*. The artist, the scientific man, the tourist, the explorer, will only have to learn for a few hours the management of this pencil, to be able to obtain similar but much more accurate results than he could with the art of drawing. Thanks to the rapidity with which the gelatino-bromide plates receive an impression—a rapidity much in excess of those of wet collodion, although that has hitherto been considered quite sufficient—he will be able to reproduce animated nature instantaneously, and to take from the life a whole crowd of facial expressions, so valuable for reference, without speaking of all the still-life objects which he can copy with surprising facility. Photography will only have had the last word when it shall have left the hands of a few specialists to enter into the daily life of every one; and that day is not far distant now that it has been proved that we can have always at hand sensitive plates produced on a large scale, and that we shall be able to buy them all ready for charging our photographic pistol. There is no need to add that, thanks to the establishments for photographic printing, either by Woodburytype or by phototype, we shall also have all possible facilities for obtaining permanent positives in any number we wish, enlarged or reduced, according to requirements. These considerations appear to me to be not out of place at a time when we are on the point of seeing our most ardent wishes accomplished. It is impossible to think too highly of the results of every kind which the beautiful discovery of which I am speaking produces; at the same time, we must all confess that, as regards the merit of having made this discovery, England occupies the first place. At the meeting of the Photographic Society of France, to which I alluded at the commencement of my letter, M. Stebbing announced that he was able to supply all demands for gelatino-bromide plates; the well-known skill of our learned colleague is a guarantee that his plates will be of the highest excellence.

M. Bardy and the Chromographe.—At the same meeting, M. Bardy submitted specimens of pyroxyline precipitated in water from solutions of different kinds, either in alcohol and ether, or in other substances—methylic alcohol, for example. He also exhibited a little instrument to which he has given the—in my opinion, inconvenient—name of *Chromographe*. As at present arranged, this instrument is in no way connected with photography, but it is

not the less interesting on that account. It consists of a layer of a mixture of glycerine and gelatine, to which is transferred, simply by applying it, a drawing or writing executed on ordinary paper with a special ink formed of a concentrated solution of aniline in water; from this above fifty proofs, facsimiles of the original, can be drawn without the addition of any other colouring matter, and without the necessity for fresh inking. It can easily be conceived that a photographic application may be given to this instrument, and I have no doubt that in a short time we shall note its having obtained some extension of this kind. M. Bary has already indicated a possible use of the layer of gelatine and glycerine for obtaining a photographic image by means of an insensible aniline powder according to Poitevin's dusting-on process. In fact, it is possible to form an image with this aniline powder on a moistened film with a mixture of tartaric acid and iron perchloride, and then to apply this film to the cake of gelatine and glycerine, and in this way to effect the transfer of a photographic image. There can be no doubt of the success of a method of this kind, as far as regards the copying of a picture in lines. I am not so certain as regards the reproduction of an image modelled in continuous tints; but it will be well worth while to study and experiment with the chromographe, to see whether it cannot be made to produce such an effect.

Award of the Prize for the Best Travelling Camera.—Before finishing an account of the meeting of the Photographic Society, I ought to mention that the 500 francs in the competition of travelling cameras has been awarded to M. Jonte. This gentleman is one of our best makers of photographic apparatus, and the decision of the judges of the competition has been received with unanimous approval. Now that the problem has been solved of obtaining rapid and sensitive films, on which I dilated at some length at the beginning of this letter, the question of portable cameras will become more than ever important. What I want to see is a complete apparatus with all the latest improvements, which, however it may be reduced in size, shall take the place, not so much if an instrument or set of tools for a specialist, as of a *vade mecum* for everybody—in fact, the photographic pencil of which I spoke before.

Lecture on the Applications of Photography to Manufactures.—In order to render complete the account of the photographic events of the past fortnight, I ought to say a few words about my lecture on the applications of photography to the industrial arts which was delivered at the "Central Union of the Fine Arts applied to Manufactures." I have no intention of exciting appreciation of my own labours; indeed, it is not of the work as personal to myself that there is any question, but of the continually increasing importance of the part played by photography in the larger number of scientific and artistic demonstrations. In my last letter, published in the PHOTOGRAPHIC NEWS of the 10th April, I spoke of the very successful lecture delivered by M. Davanne, at the Sorbonne, a strictly scientific centre, whose threshold photography has never before crossed, except in the capacity of a servant. At the "Central Union" our art has already acquired the rights of citizenship; it is now some two years ago that I was invited to deliver there a lecture which was attended with complete success. On the present occasion I can fairly say that the sympathy, and, above all, the sustained attention, with which my lecture was listened to by the audience were such as to prove that the greatest interest was excited by the descriptions and illustrations. It is impossible to recommend too strongly the multiplication of lectures such as these, for they are more than interesting; they instruct without fatiguing, and are able to do very much for the promotion of photography. I have before remarked how few there are among us—even among the learned and enlightened—who possess any accurate idea of photographic processes as a whole. But among my audience on this occasion I had scientific men, members of the Academy, professors of the University,

distinguished artists, and men of the world celebrated for the extent of their knowledge and the depth of their learning. All these were present as at an elementary school to listen to truths of which they previously knew nothing, to admire results whose causes they would never have guessed at. It is for this reason that I try to encourage the organization of similar lectures as often as possible; by making better known both the means at the disposal of the photographic art, and its applications, which are now so numerous, they do much for its promotion, as we have had constant proof after every attempt that has been made in this direction.

Congress of the Provincial Learned Societies at the Sorbonne.—While on this subject I may be allowed to speak of the part played by photography at the Congress of Learned Societies from the provinces, lately held at the Sorbonne. It is true this part was not a very large one, for I was the only one to represent our science by reading a paper; my communication, however, was received with applause by the members of all the scientific sections of the Congress who attended to hear it. The subject of my paper was a means I have recently devised of printing, simultaneously with the text, phototypes inserted in the type in the same way as is done with ordinary typographic negatives. This is an important question, and one calculated to interest highly the scientific world. In my paper, which was listened to with the greatest attention, I explained that for the positive method what we still require is the power of pulling with the text-prints, not of pictures formed by lines—that we can do already—but of photographs modelled in continuous tints. To illustrate this explanation I exhibited the negative of a phototype all ready to be inserted in the type, and I described the simple and economical method of obtaining such negatives. Want of space will not permit me to give in this place a description of this method, which is rather a collective application of several processes already known; I must content myself by pointing out that it rests mainly on the principle of the ordinary process of *phototypie*; that is to say, it consists essentially of an impression on gelatine, and of an image from which a print can be taken, formed by the action of light on bichromated gelatine. But what distinguishes the new process from ordinary *phototypie* is the fact that the two parts of the plate—the surface which gives the print on the one hand, and the hygroscopic layer on the other—are first worked and treated separately, and then bound together, so as to form one block of the required size; this block is afterwards mounted on a support just as an ordinary wood block. In a word, it is the gelatine plate of Edward's process, only treated differently as regards the chemical operations. Thanks to this process, we shall be able to print simultaneously texts and illustrations, and to produce commercially phototypic plates that can be inserted in any composition of type, or can be printed for themselves as separate figures. The whole question requires a more extended notice than can be given to it in this letter for your journal; I must, therefore, reserve any further details for a future occasion. At the Sorbonne the subject was received with great favour, for everybody was able to see how much photography has to gain from this new method of utilizing its services. These services, as we all know, are numerous enough already, but they still claim for themselves—I do not hesitate to say so—a future vaster and more extended than their past, though that even has been so enormously developed.

LEON VIDAL.

Correspondence.

M. BOISSONAS' EXTRA RAPID PROCESS.

DEAR SIR,—One of the many pleasing reminiscences of my visit to Paris last year is that of meeting the late M. Lacan and yourself at the studio of M. Franck. When you

arrived, a portrait of myself was just about to be taken by M. Boissonas' extra rapid process. The exposure was remarkably short, and the negative good, save in the lighting I was quite satisfied, however, that the process was one to be desired. Previous to your arrival, I had spent two hours very profitably in witnessing sitters after sitters (mostly children) posed artistically by M. Franek, and portraits of them taken in less than one second. This I considered exceedingly quick, as the day was somewhat dull, and the lens used was the No. 30 of Dallmeyer. I was freely admitted to the dark room, and was altogether very courteously treated. On my return home I forwarded £20 to M. Klary, and duly received in return the formula; with it I was disappointed, but, having paid so dearly for it, I followed carefully the instructions set down, but with no better result than I had anticipated: the formula was workable, but I gained no increase of sensitiveness over my own method.

By subsequent trials and diligent study of all that had been published upon extra sensitiveness, I was ultimately enabled to obtain portraits with a shorter exposure than I hitherto done; and long before the announcement that M. Boissonas had reason to believe that that incomplete formula had been issued, and that he would send full instructions to all who cared to prove their claim, I had become reconciled to my lot, and had fallen into the even tenour of my way. Imagine, therefore, how this was upset, and how readily I availed myself of M. Boissonas' offer! I submitted to him the formula received from Paris, which he declared to be false, and promised to send me full instructions. This first letter of M. Boissonas favourably impressed me, and convinced me that he was "more sinned against than sinning." In his more recent letter there is barely an allusion to pecuniary matters, but bitter complaints of the injury that his reputation has sustained, which forcibly reminds me of Shakespeare's lines—

"He that fitches from me my good name
Robs me of that which not enriches him,
And makes me poor indeed."

I did not receive the genuine formula until a few weeks ago, the delay being caused by M. Boissonas' desire to make his instructions as clear and complete as possible by having them translated. When I received the manuscript, my feelings, after a careful perusal, were very different from those actuated by the sight of the Paris document. There was about the genuine article conclusive evidence from beginning to end that the writer was a thorough master of his art, and had communicated the very essence of his studies.

No time was lost in putting the process to the test, and the result was more than satisfactory—it was astonishing. The weather at that time was simply abominable, but the process in my hands worked admirably through it all, and since the advent of better weather my exposures have been as rapid as those you saw in Paris. How M. Boissonas intends introducing his wonderful process into this country I know not, nor can I say that he intends so doing; but if so, I sincerely hope for his own sake that he will be his own agent, and that his clients will be as satisfied as myself.

I must not omit to say that the instructions are simple in the extreme, and that since reducing them to practice I have not needed further explanation.

Here it was my purpose to conclude, but I have just received a post card from M. Boissonas in which he declares that he will not (to use his own words) "sell more of the process." I can but infer from this that the annoyance he has already endured has been too severe for him to risk the ordeal again.—Yours truly,
P. M. LAWS.

PS.—It is only fair to M. Boissonas and to your readers to add that the formula published some time ago in the journals as that of M. Boissonas is really not the genuine article.

Newcastle-on-Tyne, 21st April.

RAPID DRY PLATES IN THE STUDIO.

DEAR SIR,—Will you allow me a small space to thank Mr. Ferranti for his very frank and gentlemanly reply to my letter on the subject of "Dry Plates in the Studio."

After the very capital articles from his pen which have appeared in late issues of the NEWS, there should be no great difficulty in the way of success to any one who takes up dry plates with a determination to master the details of using them; but this state of mind is absolutely necessary until the new conditions of working become familiar.

There is just one thing which cannot be too often or too strongly impressed on beginners, and that is the fact that the ordinary dark room, as used for the wet process, is utterly useless for the dry. The plates are very sensitive to the yellow rays, and the makers are often abused for sending out foggy plates, when the fault is really due to the "lighting of the dark room." I have excluded all filtered daylight from my dark room, and now use an Argand burner, having the flame covered by a glass of deep ruby colour, because the proper density can be judged only by examination against a light of standard power; and daylight, being so variable, is too deceptive. This is a most important point, for, if the negatives are too thin, they are not easily intensified, nor are they easily reduced if too dense. I think I have now discovered a way to overcome the latter difficulty, and may have more to say on the subject shortly.

I will only add that when an account of my experience can be of service to our "art science," it shall be cheerfully given.—Yours truly,
WILLIAM GREEN.

PHOTOGRAPHIC PARADOX, ETC.

DEAR SIR,—Allow me to thank Capt. Abney for the very clear way in which he has answered my question; and you, sir, for asking that men of experience should give their opinion. Although one gentleman only has done so, I think I may say that that request has practically been carried out to the very letter, when that gentleman took the trouble of writing.

Of course you threw out the hint when you used the word "relatively" in the last paragraph of your leader, but I must confess I could not understand why it was that wet plates increased in rapidity so much faster than gelatine as the light grew brighter, nor could I understand it until I came to the table Capt. Abney has favoured us with, giving roughly the number of different coloured rays in the light; but as soon as I saw that the yellow rays were very few in comparison with the blue and violet, I at once saw where the screw is loose; but it is, unfortunately for gelatine plates, too high for mortal man to reach. It was upon this point the latter part of my letter was based. I said, "If both kinds of light, &c." But a glance at Capt. Abney's paper clearly shows that both kinds of light do not increase in anything like the same proportion. The extra 90 and 95 of blue and violet rays we get in summer being little or no use for gelatine plates, there only remain roughly about 5 extra of yellow rays. Then if yellow rays are wanted, and we only get, as Capt. Abney shows, about 10 altogether in summer, this fact carries its answer with it. As I understand now, Mr. Cooper's wet plate is only relatively quicker, but the gelatine is always more rapid, that the wet if each kind of plate was tried in the same light—i.e., in a pair tried in a dull light, and a pair in a bright light—the gelatine as you, sir, suggested, in each case would take the lead.

I know that Capt. Abney will not think me impertinent if I state that I did not intend to glaze the studio with yellow glass, else we might almost as well try to photograph in the dark room; but I did not wish it to be understood that I call the light in the dark room an artificial winter light.

The above discussion having brought about the fact that in what is called white light there are so many rays—the blue and violet, for instance—not required for bromo-gela-

tine plates, and so few of the yellow which are, it has occurred to me whether those using artificial light would not do well by trying to produce a light having more of the yellow in its composition, instead of the blue and violet; if it would be practical, it might be quicker, easier to produce, and cheaper. I feel sure that many would be glad if Capt. Abney would kindly give an opinion.—Yours truly,

E. C. MURRAY.

Notes and Queries.

MARINE PHOTOGRAPHS.

SIR,—Can any readers of the PHOTOGRAPHIC NEWS kindly let me know where I may obtain unmounted photographs of shipping of all kinds, especially *shipping in motion*, or with *sails set*? I shall want to know all about the prices, which must be moderate, and the sizes may range from carte up to about 7 by 10 or 8 by 11 inches, but I must necessarily see them before making any purchases. The apparent rarity or difficulty of finding these sort of photographs is my excuse for inquiry.—Yours obediently,

MARINE.

Proceedings of Societies.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society took place on Thursday, the 10th inst., CHARLES ADIN, Esq., President, in the chair.

The minutes of the last meeting were read and approved.

THE PRESIDENT exhibited several very fair portraits which he had received from Messrs. Alder and Clark—taken by the Luxograph light. The one of himself taken by Messrs. Alder and Clark he did not exhibit, but stated that it was very much distorted.

THE SECRETARY brought the two negatives, and a transparency from one which he exposed at the previous meeting by artificial light. The one exposed to the magnesium light was the best negative in every way.

MR. SCHOFIELD also exhibited two negatives which he had exposed at the same time and under the same conditions as Mr. Chadwick, and with very similar results, for in each case the magnesium exposure was superior.

Some very fine portraits were next shown, the negatives taken by Mr. Wm. Cobb on Wratten and Wainwright's gelatine plates. These photographs were very much admired. It was said by one or two members that collodion and silver baths would not produce such soft and delicate pictures.

MR. Wm. B. WOOD next exhibited a few prints from negatives prepared with collodio-bromide emulsion of his own make, and with which he was able to work very quickly.

At the suggestion of Mr. N. Wright, who said he had seen some very excellent results by Mr. Wood's emulsion,

MR. WOOD promised to read a paper on the subject at the next meeting.

MR. SCHOFIELD exhibited a few negatives, many of which showed an insensitive patch in one corner, which was caused by a gummed ticket being applied after exposure to the back of the plate. These were gelatine negatives of both Kennett's and Bennett's plates, and a Liverpool collodio-emulsion plate also showed the same defect. A collodio-albumen negative which was treated with a ticket and the same conditions did not exhibit any such markings.

MR. JOHN LEIGH said he had had the same thing occur when developing upon a pneumatic plate-holder.

THE PRESIDENT said he had experienced similar defects, but never with collodio-albumen.

MR. SCHOFIELD also exhibited two negatives exposed at the same time to the same subject and under the same conditions: one, a Kennett's plate, exposure twenty seconds, was just rightly timed, and a very fairly printing negative; whilst the other, a Bennett's plate with only three seconds, was considerably *over-exposed*.

THE SECRETARY exhibited a beautiful little camera, with swing-back, &c., which Messrs. Meagher had just made for him, expressly for taking lantern pictures.

A vote of thanks was passed to those gentlemen who had interested the meeting, and the proceedings terminated.

BERLIN ASSOCIATION FOR THE PROMOTION OF PHOTOGRAPHY

At the ordinary meeting of the 21st Feb. a double dark slide and a lantern for the dark room were exhibited, the invention of Herr SELIGMANN. The former is constructed to carry two dry plates, placed back to back, and can be adapted to admit plates of any desired size; the latter is intended for use in the dark room when working with very sensitive dry plates, and is provided with panes of the deepest red glass, which permits only a minimum of actinic light to pass.

Herr PRUMM showed two portraits of himself, taken on gelatine dry plates of Wratten and Wainwright, with an exposure of less than a twentieth part of the time required for a wet plate. One of these had been developed with iron oxalate, the other with pyrogallic acid. For developing dry plates the speaker greatly preferred the first of these methods, because with the oxalate the development could be accomplished in about the same time as that of wet plates, while with the acid it often took from fifteen to twenty minutes. A drawback, however, in the use of the iron oxalate is that that substance soon decomposes, and has to be made fresh as required. The speaker, while confessing that the photographs exhibited left much to be desired—more especially in brilliancy, in which respect they were far from equalling those obtained by the wet method—pressed upon the Society the need for cultivating to a greater extent the dry processes, which had certainly a promising future. They were coming more and more into vogue in England, and there was no reason why the same should not take place in Germany.

Herr SELLE submitted to the meeting two portrait negatives, and a print from one of them, obtained by Herr VON SCULICHT with gelatine emulsion prepared by himself. As these were not taken in the atelier they could not be judged as regards illumination, and for the same reason the alleged duration of exposure, from three to four seconds, gave no means of forming an idea of their sensitiveness. But in respect of the excellence of the results only a favourable opinion could be formed; both plates and prints possessed fully the qualities of photographs taken by the ordinary wet process.

Herr FAHLING informed the meeting that he had also experimented with dry plates and gelatine emulsion of his own manufacture. In coating the plates he had found some difficulty in making the gelatine flow evenly, and inquired whether it was necessary to previously warm the plate. He also wished to know whether dry plates should be intensified before or after fixing.

In replying, Herr PRUMM remarked that the plates could be intensified as well before as after fixing; sometimes one method was better, sometimes the other, and experience alone was the guide as to which method was preferable. As regards coating the plate, he considered it highly desirable that it should have a temperature of about 72° F.: when the temperature of the room was not up to that mark, it would be necessary to warm the plate. To assist the gelatine emulsion in spreading equally over the plate, a perfectly clean glass rod might be used. Formerly, when it was the practice to sensitise dry plates in the bath, and a substratum of albumen was required, this substance was generally distributed over the plate by similar means, though sometimes centrifugal force was brought into play. For the latter purpose a circular wooden frame is hung up by four strings, something like the scale of a common balance, so as to have a perfectly horizontal position. The four strings are knotted together at the top, and suspended from the ceiling by a single string. By turning the frame this upper string is twisted as far as possible; the plate is then laid on the frame, and the latter let go, upon which the string will unwind itself, and communicate a quiet revolving motion to the frame. By the centrifugal action thus obtained, the albumen is distributed very evenly over the glass. The speaker expressed an opinion that an arrangement of this kind would also answer well for gelatine emulsion. Herr Reichard recommended that the glass plates should be exposed to the vapour of hot water, by which means they would be simultaneously rendered warm and moist. He believed that by this means even a tolerably thick emulsion could be flowed equally over the plate.

Herr SCHAARWACHTER complained that he had always found the plates of Wratten and Wainwright to be under-exposed after an exposure which, as he confessed, was much less than that required for wet plates.

Herr PRUMM believed this defect to be due partially to the developing. He had found it better to use more potassium

bromide than is recommended by Wainwright. He also remarked that it was an error to suppose that plates with thick films were always more sensitive than those with thin films; he had often found quite the opposite.

Professor VOGEL exhibited a drying box for gelatine emulsion plates, in which a draught is created by means of a lamp and chimney, and the air is admitted through a zig-zag tube to pass over the plate in a horizontal position.

Herr PRUMM proposed that the door of the box should be provided with an opening covered with red glass, so that the process of drying could be observed without opening the door, which was liable to give rise to marks in the gelatine during drying; but

Dr. VOGEL maintained that he had never observed such marks, notwithstanding his often having opened the door.

Herr FAHLING feared that dust might penetrate into the box through the air-way, a danger which, as Herr Prumm observed, might be guarded against by loosely stopping the tube with dry cotton wool.

A camera by Herr GRUNDNER was exhibited with a pneumatic shutter placed in the interior of the instrument behind the objective. The arrangement had been patented, is cheaper than the Cadett shutter, and possessed the advantage of not attracting the attention of or frightening the sitter.

Several samples of a new substance for backgrounds were shown by Herr BERGMANN. The same is like flock wall-paper, and is made by causing woollen dust of various colours to adhere to paper by means of some adhesive substance. It promises to serve admirably for backgrounds.

Dr. VOGEL showed a photograph of the spectra of oxygen and hydrogen taken on a gelatine emulsion plate. In the latter the lines up to the extreme red were plainly visible, a proof that the sensitiveness of the gelatine emulsion extends over the whole spectrum. Several lines are seen with ease in the photograph which are either quite invisible to the eye, or can only be faintly recognized.

At the next meeting of the Association, held on the 7th March Professor VOGEL in the chair, a letter was read from Munich announcing the formation in that city of a new photographic society, of which the well-known photographic artist Herr ALBERT has been appointed President.

A letter was also read from Herr E. BRANDT, of the firm of Brandt and Wilde, Berlin, complaining of the difficulty he experienced in working with albumenized paper in consequence of its tendency to throw up bells and pock marks, and of the liability of the albumen film to strip off from the plate. Formerly this defect was not observed, and the correspondent inquired whether it was not due to the dilution of the positive silver bath which was now universally adopted. When albumenized paper was first introduced, the formula for the bath was 1.5, in which state of concentration it was to be maintained; but now it was the common practice of manufacturers and dealers to recommend the use of only 1.20 bath for their paper. This was probably done in order to attract purchasers, who would be induced to buy the paper for the sake of the economy effected in the consumption of silver. But, as Herr Brandt observed, when the loss in time, material, paper, and even silver (in spoiled sheets) is taken into consideration, it will be seen that a more lavish employment of silver at the outset will bring ample compensation, more especially as the cuttings will fetch a higher price, and the pictures themselves be more valuable.

In the discussion which ensued on this subject Herr RULOFF expressed an opinion that the strength of the silver bath had no real influence in the production of bells. He himself had suffered much less from this annoyance than he did now, though he uniformly had used a bath of 1.10. Several other members doubted whether it had ever been the practice, except for experimental purposes, to work with a bath of 1.5, as stated by Herr Brandt.

Herr QUIDDE, however, from the experience of his own business, in which he had been engaged for over twenty years, was able to confirm the assertion that before the year 1860 a bath of 1.5 had always been used, and up to 1865 he had himself worked with one of 1.6. But this method of working was certainly more costly than the writer of the letter had stated. Between the years 1850 and 1860, when the modern practice of drawing the albumenized paper over a glass rod after silvering had not yet come into use, it was not uncommon to use up from three to four grammes of silver nitrate to every sheet of

paper, while the recovery of metal from the waste, which ought to have been considerable, was, owing to want of the necessary knowledge and skill at that time, very much smaller comparatively than it is now. At a later date, Professor Vogel, in order to fix the actual amount of silver to be used, had, as an experiment, silvered one hundred sheets of paper in a bath of 1.8, and after an accurate analysis had found that the quantity of nitrate used up amounted to at least two grammes per sheet; at the present day, with the customary weak baths, only from $1\frac{1}{2}$ to $1\frac{1}{4}$ grammes per sheet is used.

Herr PRUMM also stated that during the years 1866 and 1867 he had always recommended a bath of 1.6. At that time, some dealer or other, by way of advertising his business, had given out in his prospectus that the paper which he supplied required a bath of only 1.8; then other dealers naturally endeavoured to outbid both him and each other, until a well-known firm came down to a bath of 1.20. In consequence, photographers worked now with much weaker baths than was formerly the case, and this was probably the cause of numerous defects. A bath of 1.12 the speaker held to be decidedly too weak. By a weak bath the albumen is dissolved, by a strong one it is coagulated; even a bath of 1.9 dissolved some of the albumen. As regards, however, the formation of bubbles or bells, and the separation—that is to say, dissolving—of the albumen film, he drew attention to the fact that these two defects were due to quite different causes, and were in no way dependent on each other. The cause of the last-named fault had been sought in the low temperature of the bath; but, in the speaker's opinion, it was owing to the albumenized paper itself, and more especially to the original plain paper; for only one kind of paper was used, and that came all from the same manufactory. His own belief, after much experience, was, that the best means of avoiding the dissolving off of the albumen film was to employ a now silver bath of about 1.7—in any case, not less than 1.9—and if the defect was still found to prevail, to leave the paper longer in the bath, and to avoid the use of a glass rod for draining off.

Dr. FRIEDLANDER exhibited a series of instantaneous photographs of a horse on the trot, taken by Mr. Muybridge at San Francisco. These pictures depict the horse, the driver, and carriage merely as shadows on a light background; the outlines are much blurred, probably because accurate focussing for every position was an utter impossibility. Very remarkable is the varying position of the horse's legs in the different successive photographs.

Several positives for enlarging from were sent for exhibition by Herr WILDE, of Görlitz. These positives were perfectly transparent, even in the deepest parts, and showed no signs of graining. They are taken on dry plates by exposure in a copying frame under a negative. Herr Wilde also prepares them on emulsion paper, afterwards drawing off the film and transferring it to glass.

A camera shutter, capable of being moved from a distance, was shown by Herron MARTINI and BERGMANN. It consists of a simple trap fixed in front of the objective, and is raised and lowered by pulling a string. An objection was raised that in working the shutter the camera was liable to be shaken, but Herr Martini replied that there would be nothing to fear in this respect if the instrument rested firmly in its stand.

Herr SCHAARWACHTER showed a number of examples of a process by Messrs. Werner and Schumann in which a water mark is produced in paper by a photo-mechanical method. From the original a copy in relief on chromo-gelatine is obtained by photography; from this a metal stereotype plate is taken, and the water mark pressed into the paper by means of a hydraulic press. This press must work very smoothly, or the mark will be unequal. The specimens exhibited were very accurate and clear; letters in large or small type, written characters, drawings, even portraits from cartes-de-visite, with all the half-tones visible, were impressed in the paper.

Herr RULOFF showed some examples of plates worked by Herr Boll's electric process; among them were a couple of portraits of the same person, each exposed for ten seconds, the one with, the other without, the employment of electricity. That which had been worked by the electrical process showed a much greater degree of penetration than the other one, though the general effect was by no means so brilliant as had been represented by Herr Boll. Herr Ruloft remarked that the electrical current employed was a very weak one; with a stronger current he hoped to obtain a better effect.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—The next meeting of this Society will take place at the House of the Society of Arts, Adelphi, on Thursday next, May 1st, at 8 p.m., when papers will be read by Mr. E. Foxice on "The Continuing Action of Light in Carbon Printing," and Mr. Harrison on "Reflectors."

THE ABSORPTION OF THE ULTRA-VIOLET RAYS OF THE SPECTRUM BY ORGANIC SUBSTANCES.—An investigation has recently been carried out by Messrs. Hartley and Huntington on the connection between chemical constitution and diacritical quality. For this purpose they used the apparatus formerly employed by the late Dr. W. A. Miller, with a few slight alterations. The apparatus consisted of a spectroscope attached to a photographic camera, the prism and lenses being of quartz. The electric light consisted of sparks of great intensity passed between metallic electrodes. To produce the sparks an induction coil, capable of giving a 7-inch spark in air, was excited by five cells of Groves' battery. A Leyden jar was interposed between the coil and the electrodes, each surface of the foil measuring seventy-two square inches. The electrodes found to answer best were points of nickel wire, containing a trace of copper. Cells of glass, with quartz sides, were used for holding liquids under examination. In order to measure the degree of absorption exercised by different substances, the example of M. Soret was followed, and the lines of cadmium were taken for the purpose. M. Mascart has measured the wave-length of these lines both for the visible and ultra-violet rays. Dr. Miller failed to trace any connection between the chemical complexity of a substance and its actinic absorption, but Messrs. Hartley and Huntington found that:—(1). The normal alcohols of the series $C_n H_{2n-1}$ are remarkable for transparency to the ultra-violet rays of the spectrum, pure methylic alcohol being as nearly so as water. (2). The normal fatty acids exhibit a greater absorption of the more refrangible rays of the ultra-violet spectrum than the normal alcohols containing the same number of carbon-atoms. (3). There is an increased absorption of the more refrangible rays corresponding to each increment of HC_2 in the molecule of the alcohols and acids. (4). Like the alcohols and acids, the ethereal salts derived from them are highly transparent to the ultra-violet rays, and do not exhibit absorption-bands. With the idea of ascertaining whether isomeric bodies exhibited similar or identical absorption spectra, a series of benzene derivatives was examined: one of the most interesting results obtained from these benzene series is that the photographic absorption spectra can be employed as a means of identifying organic substances, and as a most delicate test of their purity.—*Photographic Journal*.

COPYING DRAWINGS.—There has been furnished a brief account of the handy process used at the School of Mines (Columbia College) for copying mechanical drawings and plans by a sort of photography. The original drawing must be on tracing or transparent paper. No camera is required. The process simply consists in laying sensitized paper with the prepared side uppermost on a board covered with two or three thicknesses of flannel, spreading the tracing that is to be copied on prepared paper; covering the whole with a sheet of glass about three-eighths of an inch thick, and exposing the arrangement to sunlight for six to ten, or diffused daylight from sixty to ninety minutes. The copy is then to be washed in clean water thoroughly and hung up to dry. P. Barnes related these particulars recently before the American Institute of Mining Engineers, and specified also the method of preparing the sensitized paper. One solution is made of $1\frac{1}{4}$ ounces citrate of iron and ammonia in 8 ounces of water; another of $1\frac{1}{4}$ ounces red prussiate of potash in a like quantity of water. The water must be pure. These solutions are to be mixed and kept in the dark or in a yellow bottle. The mixture is to be applied to paper on one side only, with a sponge, most conveniently by twice passing the sponge over, first quite wet, and secondly squeezed nearly dry. The paper is then hung by a corner to dry, and must then and afterwards be kept in the dark till used. It should be of a full yellow-bronze colour when prepared. It will be noticed that this method differs from one that has been previously described, in the circumstance that a mixture of the solutions is used, instead of two separate dippings of the paper, but the probability that the mixture could be so used was then foreshadowed. The whole process is new, and has lately become popular from its convenience.

To Correspondents.

AN OLD BUT IGNORANT PHOTOGRAPHER.—Add a strong solution of protosulphate of iron to the gold solution. This will precipitate the gold as a black powder. Wash this precipitate with dilute sulphuric acid to remove traces of iron, then rinse well, and redissolve with nitro-hydrochloride acid, and so make chloride of gold in the usual way.

R. G.—It is altogether a matter of taste. The tone is black, sometimes a greyish or a blue-black. Those who like such a tone will admire them. Those who prefer a warm tone will prefer a gold-toned print. You should see examples before investing.

A CONSTANT SUBSCRIBER.—The spots on the print you forward may be due to various causes. They resemble very much the spots produced by particles of bronze powder, often used in the "gold" printing on the back of the mount. As your print is removed from the mount we cannot tell whether any "gold" printing was present. The spots, however, suggest such an origin. Sometimes they are from other causes. Albumenized paper which has been long kept in a damp place will develop a mixture fungus which causes similar spots.

R. J. S.—The firm in question no longer exists, nor does the tent. It has been superseded by much superior appliances. It answered the purpose moderately well, and was cheap and simple; but many of the dark tents which have been described in our pages, and also those in commerce, are much more efficient.

AMATEUR.—It is wise to master the wet process first, and then learn a dry process.

ZULU.—An ordinary dark slide, such as is used in the wet process, will answer for gelatine plates, provided it is light-tight. Lack of density in such cases may be due to various causes. Over-exposure is a very common cause; the presence of too much light in the dark room is another cause. A stronger solution of pyrogallie acid will help you. The plate must be very thoroughly washed before applying pyro and silver; and it is wise to apply the acid pyro solution without silver first, not adding the silver until the pyro solution flows evenly.

J. L. R.—Precipitate with a solution of sulphate of iron, leaving the lead salt in solution.

FOCUS, JUNR.—The case of the opals appears at first sight very perplexing; but there is, we think, a very definite solution to the problem. There is a fact to be remembered at the outset, which is very often quite overlooked; that is, that the lens is a window through which light passes, as well as an object-glass. When working with full aperture or a large aperture, the light so admitted is apt to produce something foggy, over-exposure; and this is, we think, the case in the instance you describe. If you carefully exclude extraneous light by shielding the lens, you will, we think, get rid of the trouble.

B. D.—Prints should always be well rinsed after toning before immersing in the hypo fixing bath. Any trace of acid in the hypo solution will cause decomposition, and induce sulphur-toning, which will finally issue in fading and the print turning yellow.

X. Y. Z.—The only method we can suggest for obtaining a situation as "improver" is to advertise. There is no special system or scale of terms upon which such matters are settled. In some establishments you will have to pay a premium, and in some you may obtain some remuneration for your assistance.

JUNIOR.—Toning opal pictures and collodion prints for transfer, besides giving a deeper, blacker colour, materially improves the picture by giving it clearness and brilliancy, removing a sunken smoky effect which often characterizes the developed image when examined by transmitted light.

F. S. B.—So far as we know, it is customary to varnish collodion images on opal before colouring them in water colours. It is not a branch of the art in which we have had much experience, nor has much been published on the subject. Matt varnishes are used in most cases. In some cases we believe that a protective varnish is first applied, and then a matt varnish for effect and to make the process of colouring more easy.

F. C.—We wish you success. Do not worry about the obligation. It will wait.

PATENTS, TRADE-MARKS, &c.—We have made arrangements to answer through our columns any questions which may be addressed to us respecting patenting inventions and the registration of trade-marks and designs. As these subjects are of growing interest and importance, we invite all our readers in doubt on any point to write to us. It is almost needless to say we make no charge.

Several correspondents in our next.

The Photographic News, May 2, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AS AN AID TO ANTHROPOLOGICAL SCIENCE—

THE IDENTITY OF PHOTOGRAPHIC WORK—POIKILOGRAPHY

Photography as an Aid to Anthropological Science.—The

employment of photography in the study of anthropological sciences has already led to some valuable results. But a short time ago we referred to a German publication containing many hundreds of photographs showing races and types of mankind throughout the globe. By the aid of photographic portraits in sufficient number of the many distinct types of human beings it was possible to classify the races in a far more intelligent manner than had hitherto been attempted. The work published in Hamburg, if we remember rightly, was necessarily very expensive, and embraced rather too wide a range to be included even within the space of several volumes, and since then the subject has been taken upon many sides, the various students occupying themselves only with certain sections of the human race. In Great Britain an endeavour is being made by the Anthropological Society to collect photographs of types, and it is not so long ago that we conveyed in these columns the invitation given by that Society to photographers, both amateur and professional, throughout the country to aid in the work by forwarding portraits of any strongly-marked families which have been known to reside for some time in certain districts. Dr. Darwin, as our readers know very well, has frequently made use of the camera in illustrating his works, and he was fortunate enough to obtain the co-operation of the late Mr. O. G. Rejlander in carrying out some of his ideas. Some studies illustrative of "expression" were among the happiest results of Mr. Rejlander, and most people have seen woodcuts of these, signifying horror, fear, disdain, &c. These studies have been copied into Continental journals, and scattered broadcast throughout the world, the model in several instances being no other than Mr. Rejlander himself, who threw himself into Dr. Darwin's work, and carried out that gentleman's ideas in an eminently satisfactory manner. Recently a very extensive collection of photographic portraits have been presented to the Anthropological Institute by Dr. Hayden, whose studies relate especially to the Indian tribes of North America. In Dr. Hayden's collection are represented no less than seventy distinct tribes of Indians, so that a most interesting study may be made of these fast disappearing races. It is of course the faces that form the main point of interest in these photographs, but the pictures show in many cases the native dresses of the people. In some instances there is still every appearance of savagery in the personal adornment, in others we see nothing but civilised garments. Some of the men are shown with their native implements of warfare, with scalping knife, and tomahawks, and scalps as well while others, by way of contrast, are shown in the photographs depicted in the coat-tails of the homely citizen. This collection of Dr. Hayden's has recently given rise to an animated discussion, it seems, owing to the supposed resemblance of one out of the number of portraits to that of Mr. Ruskin. It is that of an Ojibbeway Chief rejoicing in the picturesque name of "Hole in the Wall," and so like is his portrait to that of the distinguished art critic, that some aver the picture is one that Mr. Ruskin must have sat for. Whether busybodies or practical jokers have withdrawn the original "Hole in the Wall" and substituted a picture of Professor Ruskin, or whether the portrait in question, though resembling the latter personage, is really that of an Ojibbeway, is still a moot point, and one that is yet exciting interest.

The Identity of Photographic Work.—The *Athenæum*, in discussing the question of genuineness in this case, thinks it hardly likely that Prof. Hayden has been imposed upon by some American wag, and a *carte* of Mr. Ruskin been foisted on this collection; and that journal further suggests

that the matter could easily be set at rest by examining the name of the photographer on the back of the portrait, and if it proves to belong to the Survey, then there will be an end to the suspicions as to its genuineness. We should hardly like to pronounce an opinion upon such evidence alone. It by no means follows that because the mount to which a photograph is attached bears a name, that the latter is the photographer who secured the picture. In the event of any roguery having been practised upon Dr. Hayden, we may pretty well be sure that he who perpetrated it took good care to secure first of all a mount of the same nature as those upon which the genuine pictures are mounted. Deceptions of this kind, we are sorry to say, are not confined to practical jokers. In conversation with Mr. William England one day, we asked him if he were acquainted with that part of the Tyrol known as the Glockner district, in which the Gross Glectner mountain and the Pasterzen Glacier formed the centre. Strange to say, he had not visited that part of the country, although, as our readers know, there is scarcely any Alpine valley or range which Mr. England has not only seen, but depicted in the camera. What was our surprise, then, but a few weeks afterwards, when looking over a collection of Swiss and Tyrol scenes, to see a large picture of the white monarch of the Tyrol, and the famous Pasterzen Glacier, with Mr. England's name under it as the photographer. Mr. England, singularly enough, happened to be at hand at the moment—he was a guest at the house where we ourselves were a visitor—and straightway the pictures were carried to him. Naturally enough, the first idea was that Mr. England, being a considerable traveller, might have forgotten the circumstance of his visit to the Gross Glockner. But no, the explanation simply was that the photographs were the work of another, who had affixed Mr. England's name to the mount; or, what was more likely, a supply of the English photographer's cards had been secured for the purpose of mounting the photographs. Another instance came under our notice last year. Paris photographic portraits have a high reputation, especially among visitors to the French capital, and some American photographers who were paying a visit to the Exhibition took the opportunity of examining the cartes and cabinets exposed for sale in the French metropolis. What was their surprise to see portraits that were well known to be the production of American firms, mounted upon cards with French names. The shopkeepers knew that the Americans and English were among their best customers, and it was not likely that either of these nationalities would readily purchase their own ware. So a little bit of deception had been practised, which no doubt proved profitable in the end. Therefore we would warn those who are not conversant with such matters to give heed how they take the name printed at the back of a photographic mount as proof positive of the picture itself having been produced by the firm indicated.

Poikilography.—Poikilography is not a pretty name, however charming the pictures may be produced by it; and if it is true, as *Autotype Notes* says, that a National Fine Art Company is now engaged in exploiting the process, we urge the company in question to change the name. Bearing in mind the school-boy legend "Porkus est nicehus," we may assume that Poikilographs are nice also; but since we have the assurance of Shakespeare that a rose by any other name will smell as sweet, there can be no reason for abandoning a term which is rather more suggestive of sausages or peas-pudding than anything of an art character. The process is described as the art of placing a photograph on one side of a cloth or canvas, and painting by hand the other—no reason, surely, why it should be called Poikilography.

SOME CRITICAL REMARKS ON EMULSIONS.

BY M. QUEVAL.*

THE emulsion process, though now scarcely beyond the stage of infancy, is destined, as I believe, one day to replace

all other wet and dry processes. Many formulæ have been published for the production of a good emulsion, but they are all tedious and difficult in practice, and I recommend sincerely not only amateurs, but also professional photographers, to obtain their emulsion, as they have for a long time done with pyroxylic and the other articles they use, by buying it. Last summer I took some six or seven hundred negatives with emulsions purchased at the establishment of Puech, and by so doing I have saved myself from much discomfort and loss of time.

The results obtained by this process resemble in many respects those of wet collodion, only they are often superior to the latter. Though, however, the emulsion process offers many advantages, it cannot be denied that while seeming to be very simple and easy, it presents as many difficulties as the other dry processes. These difficulties I propose now to enumerate, at the same time pointing out the means for overcoming them. However well prepared emulsions may be, though produced by the same manufacturer and with the same formula, it is seldom that any two will give the same results; it is consequently advisable to test each bottle in order to determine its qualities and its defects.

The sensitiveness of emulsions may vary in degree in the proportion of from one to four—that is to say, we may have them acting very rapidly, normally, slowly, or very slowly. In the first case, they are of great value for taking badly-illuminated objects; but photographs taken in them are subject to the phenomenon of irradiation, which renders their employment very difficult for certain views—such as the interiors of buildings lighted by glass windows. In the second case, the irradiation diminishes with the sensitiveness, and can be altogether prevented by using the substratum mentioned below; the development also is facilitated. In the third case—that is, when the sensitiveness is much less—an exposure is required about three or four times as long as that with wet collodion, but then there is scarcely any irradiation, at least not in the outlines of objects that cut the sky. Development is much slower, but much cleaner and more certain, and the results generally are finer. Lastly, when the plates are known to be very slow, we shall obtain the finest results, provided always that we can ensure a sufficiently long exposure. In such very slow plates I have never observed any irradiation, even in views of interiors, and it is consequently not necessary to colour or blacken them. There is no cause to be afraid of the length of exposure up to seven or eight times that required for wet collodion, the plates are easily developed, and are as intense as can be desired.

As a general rule, we may reject every emulsion which requires to be intensified with silver; an emulsion that is properly prepared ought to develop perfectly without intensification. To the absence of metallic deposit is due the great delicacy and transparency of the negatives obtained by this process. There is another reason why intensification must not be resorted to, and that is the extraordinary delicacy of the bromide film. If it be impossible to dispense with intensification before fixing, the negative must be thoroughly washed with acidulated water, to remove any trace of ammonia. It is seldom that the alkaline developer has not penetrated beneath the collodion by some invisible hole, and as a defective place of this kind can never be properly washed out, the silver solution will in its turn effect an entrance, and be the cause often of numerous spots, which it is impossible to foresee or to get rid of. When the plate is intensified after fixing, the manipulation is easier, as it can be carried on by daylight; but it often happens that the hyposulphite introduced at the above mentioned holes can be completely eliminated by washing, and the silver penetrating again in the same way will produce spots which, though different from those before mentioned, will equally spoil the negative. It is therefore very important to choose an emulsion which shall not be subject to these defects.

One of the most frequent causes of failure in working with emulsions is the insufficient adherence of the film to the plate; it is almost impossible to develop without accident a plate on which the emulsion has merely been flowed. There are different methods of giving the film the requisite firmness to resist all the operations it has to undergo.

(1). After having cleaned the plate, rub it with a cotton cloth or a piece of swanskin in which you have placed some powdered talc; this removes the powder by rubbing it lightly with another cotton or linen cloth, taking care not to rub off the greasy smoothness produced by the talc. You will thus have a plate easy to develop, and a film not liable to be removed. I recommend this method more especially to amateurs, but only to those who do not print many copies from the same negative, for the negatives obtained in this way, however well they may be varnished, succumb after being copied a few times.

(2). I have tried, but unsuccessfully, substrata of gelatine and albumen, but a half or one per cent. solution of very pure caoutchouc in rectified benzine has given me almost satisfactory results. I say almost satisfactory, because it is necessary to filter the solution very carefully, and when this effected through ordinary filtering paper its pores soon get stopped, and the filtration is arrested. It also occasionally happens that the benzine, though it does not completely dissolve the paper, will slightly disintegrate it, and will carry away some of the particles which destroy the purity of the film produced on the glass plate. Perhaps this defect may be got rid of by filtering the solution through glass wool; if so, I should recommend this method in preference to every other. Films coated over with this substratum develop well, and without coming off, and have, after varnishing, comparatively sufficient hardness.

(3). Another method consists in preparing a solution of caoutchouc in benzine, and coating with it the edges of the plate, either before applying the collodion, or after laying on the collodion and before exposing, or after exposure and before developing. I recommend the last of these plans because the benzine varnish will close all the apertures by which the developing liquid could insert itself beneath the collodion. Now, when a plate is removed from the slide, it will be frayed in several places by coming into contact with the sides of the latter, and it is necessary to close these abrasions with the greatest care. By this method we can obtain after varnishing a certain amount of cohesion; but it requires very great precautions, and I should strongly advise amateurs to confine themselves to the first method that I have described.

When the emulsion contains an organic sensitizer—quinine, or any other of the same kind—it is advisable to eliminate it before allowing the alkaline developer to act. By this elimination we can sensibly shorten the time of exposure; but it must be either completely carried out, or else abandoned altogether, and it can only be effectually accomplished by liberal and repeated washings with alcohol. If sufficient alcohol be not at hand, it is better to expose for a little longer time, and to omit this preliminary operation altogether; in this way we avoid the granulations produced by the particles of quinine that are not dissolved. When the emulsion contains no preservative, the washing with alcohol will produce no inconvenience, and will render the collodion more pervious to the developing solution. Of course the washing with alcohol must be followed by copious washing with water until the greasy marks disappear.

Though emulsions may differ from one another considerably in point of sensitiveness, there is another substance which never gives the same result, and that is ammonium carbonate. Were it not that ammonia dissolves silver bromide, it would be best to employ a solution of that substance as a developer; but as it is, ammonium carbonate is preferable to all other substances, only it must be carefully selected in hard semi-transparent lumps that smell strongly of ammonia. As soon as it turns of a

dull white colour it loses many of its properties; on this account it is better to keep a standard or saturated solution of the salt in a well-stoppered bottle, which itself must be renewed from time to time.

It is impossible to give a precise formula for developing bromide plates; in the first place, because two bottles of emulsion often give such different results; and then because the ammonium carbonate is itself a most unstable substance. All the formulæ are good provided that we first mix together all the three substances—potassium bromide, pyrogallic acid, and ammonium carbonate—or that we flow over the plate the bromide and the acid—or the bromide and the carbonate, and then the third substance separately. The only essential condition for developing free from fog is to use from the very first enough potassium bromide, for it is at the beginning of the development that the plate has the greatest tendency to fog. So soon as the image has almost completely made its appearance, the pyrogallic acid or the ammonium carbonate may be gradually added up to the point of the required intensity.

If we make use of an emulsion that requires to be intensified with silver, it is indispensable to wash the plate with water slightly acidulated, so as to remove all trace of alkali, which would show itself either in scattered spots or in a general veil. But I cannot too often repeat that a good emulsion never requires to be intensified with silver nitrate, and that intensification is always the cause of defects and failures which it is desirable to avoid.

When travelling, the great inconvenience of bromide plates is the fixing, to a certain extent on account of the fixing substance, but more because of the large quantity of water required for washing thoroughly. It is true they may be treated with potassium cyanide, and will then not require so much washing; but it is more advisable to dispense altogether with the use of this dangerous substance, which acts sometimes with so much energy on the delicate film as to endanger its cohesion.

Hyposulphite of sodium dissolved in common water in all proportions from fifteen per cent. is therefore preferable from every point of view. But this substance is very dangerous to the vessels and the other chemicals that must be packed up when a long journey is in prospect; it must therefore be isolated completely, and the flasks or beakers in which it has been used must be cleaned with the greatest care.

Another plan is to keep the plates, after they have been developed, in a closed box, and to fix them on the return home, but this operation is then much more difficult. The plates must first be moistened with alcohol, notwithstanding which incurable tumefactions will often occur, which might have been avoided by fixing directly after development.

The diversity of sensitiveness of which I have above spoken may be turned to account, and, instead of being an inconvenience, may become an auxiliary. On a piece of paper gummed to the back of each plate write the words "quick," or "slow," and carry with you on your journeys some plates of each kind. A view presenting great contrasts of light and shade will succeed best on a rapid working plate, while one that is equally illuminated and of a uniform tint can be preferably taken on one of the contrary kind.

Notwithstanding the small difficulties that I have enumerated, the emulsion process will nevertheless remain the greatest advance that has been made in dry plate photography. When we have attained the result of causing the film to adhere firmly, and to make it as sensitive as one of wet collodion, there is no doubt that this process will advantageously replace all others now in use.

ON WAVE-BATH HOLDERS.

BY H. J. BURTON.*

I PROPOSE to make a few remarks upon that kind of bath-holder known as the wave-bath, for I am not yet convinced that the wet process is either dead or dying, notwithstanding the great improvements recently made in dry plates.

Some few years ago I called attention to this particular form of bath, but am inclined to think that photographers have not fully appreciated its merit for studio work. These baths are used exclusively at the Autotype Company's Works, and have been so for the last seven years, therefore full opportunity has been afforded for testing their capabilities. Various materials have been used from time to time, and much useful information gained in their construction. I am convinced that if used for a short time in any studio, the wave-bath would become the favourite, and dipping-baths retained for out-door work only. I will point out a few of the advantages to be gained by the change. Strucky plates: these are unknown, for this reason, but whilst the plate is sensitizing in the wave-bath, it of course lies face upwards, and in that position the ethereal solvents that leave the collodionized surface do so at right angles to the surface of the plate, and have a very thin stratum of liquid to get through to escape. In dipping-baths these solvents have to traverse the whole length of the plate, and in doing so form streaks, by keeping the nitrate solution away from the plate while they are travelling to the surface. I once emptied some bath solution from a wave-bath into a dipping-bath to do an out-door job; I knew the bath was in good order, and therefore was astonished to see the first plate out of it covered with streaks.

As the wave-bath is made with a light-tight cover the dark room door does not require to be closed, except to remove the plate to the dark slide. A slight rocking of the bath is equivalent to lifting the plate up and down an indefinite number of times, as is necessary with the dipping-bath, to remove the greasiness from the surface, and it does it much more completely too. By simply pressing the bath down so that the solution runs towards the well, the plate is drained in the most perfect manner, and without the slightest occasion to close the dark room door. Being in an almost air-tight chamber, a plate may be drained for half-an-hour, and be none the worse for it; at the same time be thoroughly shielded from light as well as from dust.

The advantages of being able to keep plates always ready for use will be considerable in a large business, as with a couple of wave-baths, plates may be always ready to put into the dark slide in the very best condition; there is also the great cleanliness in the dark-slide and camera, as well as a saving in silver through the more perfect draining of the plate.

A plate of a given size may be sensitized in half the quantity of solution required for it in a dipping-bath. The bath-solution will keep in order for a longer time, on account of the larger surface of solution that is exposed to the air. It is also much more easily cleaned out, as the hand may be got into any part of it.

With the present form, it is only necessary to occasionally black-varnish the inside, and give a coat of paint to the outside, to be as good as new; therefore, with ordinary care, it would last a lifetime. In ordinary portrait work where the plates used are up to 10 by 8, I should recommend a bath that a 15 by 12 plate would go into, for this reason: when a plate is draining in a bath that is only a little larger than itself, it must necessarily do so with the base of the plate in an horizontal position; but if the bath were larger, it would be possible to so place the plate that one corner of it should be the lowest, and therefore it would be drained most perfectly.

I will finish these remarks by observing that the best way to clean the bath out is to use a little weak solution of cyanide of potassium and a rough piece of sponge, afterwards

* Autotype Notes.

rinse out with clean water, and finally dry with a wash-leather that has been washed and wrung out, and is still damp. Just before pouring in the bath-solution, dust out with the plate dusting brush.

TWO RAPID PROCESSES.

OUR American brethren are considerably exercised at present on the subject of rapid wet processes; but they have not yet recognized the fact that rapid gelatine plates surpass in sensitiveness any form of wet plate. Our Philadelphia contemporary, in a recent issue, publishes two alleged rapid processes. The first, without a parent's name, is as follows:—

SILVER BATH.

Take any quantity of nitrate of silver, place it in an evaporating dish, and heat, not merely until liquefied or fused, but heat to a red heat for at least two hours. This, if properly done, will burn out all impurities. Allow it to cool, and dissolve in pure water (prepared by adding two or three grains of silver to the ounce of water, and sunning until clear). Reduce to sixty grains to the ounce, and of a thirty-grain solution of iodide of calcium add all it will take up, or until it remains permanently milky. Now reduce to forty grains with the prepared pure water, shake, and sun until clear. Decant, or filter through chemically-pure filtering paper, and add C. P. nitric acid until it tests decidedly acid; let stand twenty-four hours, and add of a saturated solution of sal-soda, one drop at a time, so long as it will take up without showing permanent milkiness. Sun until all is clear, and you will have a bath that will work quick and clear as long as there is anything left of it, provided it is kept in a temperature of not less than sixty degrees, and allowed to stand open when not in use.

Developer.

No. 1.—Water	32	ounces
Iron	2	"
Alum	3	"
Loaf sugar	$\frac{1}{2}$	ounce
Acetic acid	2	ounces
No. 2.—Water	32	ounces
Iron	2	"
Sulphate of soda	$1\frac{1}{2}$	"
Concentrated ammonia	6	drops
Acetic acid	4	ounces

Mix equal parts for use.

For stock, the above can be mixed double strength, and reduced to meet the requirements of the negatives. It acts slowly, but keeps at work a much longer time than any other developer, so that your negative is under control. When the detail is all out, and you wish more contrasts in the lights and shades, take of the bath solution two or three drops of silver in a small vial (a wide-mouthed iodide four-ounce bottle answers the purpose), and in a separate bottle have a three-grain solution of pyrogallic acid mixed as follows: Pyro three grains, citric acid two grains to the ounce of solution. Flow the plate with this, and pour off into the vial containing the silver. Now flow on and off the negative until all the intensity you wish is obtained. If the plate has been over-exposed, so that the image flashes out and then sinks in, wash off the developer at once and clear; if not intense enough, proceed with the pyro as above.

RAPID COLLODION.

For plain stock collodion, take equal parts of Atwood's alcohol and concentrated sulphuric ether; cotton, six grains to the ounce of collodion. First soak the cotton in a weak solution of alcohol and ammonia (one drop concentrated ammonia to the ounce of alcohol); squeeze out dry as possible, then rinse out once in a little alcohol, again squeeze dry, and add to the stock of alcohol; shake up, then add the ether. Shake until the cotton is dissolved.

Samples of cotton of the same brand differ greatly, both in rapid working and in the quantity it will take to make the collodion the required thickness to give best results. For this reason it is always best to test a batch of cotton by mixing and trying a little of it before preparing a quantity.

As a rule, Hance's Delicate Cream Cotton will make the most rapid collodion, but this sometimes proves worthless as to rapidity.

Rapid Iodizer.

Iodide of ammonium	4 $\frac{1}{2}$	grains
Iodide of lithium	$\frac{1}{2}$	grain
Iodide of calcium	$\frac{1}{2}$	"
Bromide of cadmium	2 $\frac{1}{2}$	grains
Bromide of lithium	$\frac{1}{2}$	grain

to one ounce of pure collodion.

To Prepare.—Take the amount of alcohol you wish to iodize, place the iodides in a mortar, and add alcohol, and grind to saturation, and pour off into a separate bottle. Repeat adding the alcohol and grinding until all the iodides are dissolved. Then do the same with the bromides, and pour into the iodizers. With care and proper grinding no water need be added, although a little water, free from any acid reaction, will add somewhat to the rapidity. The longer this iodizer is made up the better it will work. Make for convenience, so that one ounce will iodize sixteen ounces of plain collodion; or if you only wish to iodize eight ounces at a time, make up so that one ounce will do for eight ounces. The plain collodion should be made up in stock, and not less than one month old; six months is better.

After iodizing, it takes ten days to cool, and five days in hot weather, before it is ripe enough to work its best. If kept cool it will improve until about three to six months old, though usually two weeks to three months old will give the quickest and best results.

Caution.—In mixing the iodizer with the plain collodion, always pour the collodion into the iodizer, a little at a time, and shake as you add, until the collodion is all added.

THE RAPID PROCESS OF JAMES INGLIS, MONTREAL, CANADA.

THE second rapid process is described as being sold as a secret to the gullibles by Mr. James Inglis. We copy it from the printed circular supplied by him.

PURIFIED WATER FOR SILVER BATH.

Soft water	1	gallon
Kaolin, or French chalk	2 to 3	ounces
Nitrate of silver	$\frac{1}{2}$	ounce

Put this in the sun until perfectly cleared, which will take about a week.

NEGATIVE BATH.

Nitrate of silver (pure)	4	ounces
Water (purified)	48	"

When dissolved, add just sufficient bicarbonate of soda to cause a slight precipitation, which will only require a few grains. Iodize by pouring in about one-fourth of an ounce of the collodion. Now put in the sun for half a day or so. Filter through clean cotton-batting, or a small piece of sponge; filtering-paper is very uncertain. Now add from two to three drops of C. P. nitric acid, or enough to make it work clear. Keep up the strength of the bath by frequently adding to it a fifty-grain solution made the same way.

PLAIN COLLODION.

Alcohol	16	ounces
Ether	16	"
Gun-cotton	192	grains

Iodizer No. 1.

Double iodides	240	grains
Double bromides	96	"
Alcohol	8	ounces
Ether	8	"

Dissolve the iodides and bromides, first in the alcohol, then add the ether, and let settle before using. There will be a heavy precipitate.

Iodizer No. 2.

Iodide of ammonium	144	grains
Iodide of cadmium	96	"
Bromide of cadmium	48	"
Alcohol	8	ounces
Ether	8	"

To six ounces of plain collodion, add one and a half ounces No. 1 iodizer, and one and a half No. 2 iodizer. When the collodion becomes too white, add iodine to keep it a nice straw colour.

TO PREPARE THE DOUBLE IODIDES AND BROMIDES.

<i>Bromides.</i>			
Bromide of potassium...	175 grains
Bromide of cadmium	220 "
<i>Iodides.</i>			
Iodide of potassium	293 grains
Iodide of cadmium	136 "

Dissolve the two bromides and iodides separately in a small quantity of water, and evaporate them over a gentle heat sufficiently to allow them to crystallize when cold.

<i>Developer.</i>			
Iron	6 ounces
Nitrate of potash	3 "
Acetic acid, No. 8	8 "
Water	80 "
<i>Re-developer.</i>			
Iron	1 ounce
Citric acid	1 "
Water	80 ounces

By using it as weak again, with (say) one drop of silver solution, and patiently keep re-developing, you will be astonished to see what an amount of detail can be brought out of an under-exposed negative.

THE CARBON PROCESS IN AMERICA.

THE somewhat acrimonious discussion on carbon printing which has been maintained in America for some time past has, for the present, abated. Mr. C. Gentile, of Boston, an apostle of carbon, writes to the *Philadelphia Photographer*, an opponent, in response to some attacks, as follows:—

"If your readers will peruse the journal carefully they will find in Dr. Vogel's letter from Paris a complete refutation of the statement made by Van Loo to Gatehel, in which he says, 'no one was using carbon for portraiture in Paris,' and that 'Wallery, the leading artist there, had discharged his operator (of carbon work), an experienced one, and gave up all hope of success after a six months' trial.'

"It would be impossible for an 'experienced' operator in carbon to fail in getting out good prints in Paris during six months' work. Van Loo must have seen so many processes of printing in the Paris Exposition that he got slightly mixed up. I would refer your readers to page 339 of your journal for November, in which Dr. Vogel states, 'Rentlinger is represented with small and large pictures, all equally well.' A special interest is excited by some large pictures of his made by the carbon process. And, again, farther on, the Doctor says, in the same communication, 'The carbon printing process has found in France quite a number of admirers. Liebert, formerly in America, works exclusively with this process.' What does Van Loo think of that? The Doctor continues: 'Rentlinger has exhibited a large carbon print; Rousseau, Provost, Cavette, Frank, Fabre, &c., exhibit carbon pictures; some of them are in life-size, and very good. Braun, of Dornach, is ahead of all,' &c. After reading Dr. Vogel's letters, your readers will be convinced that the carbon process is not abandoned in France, nor is it likely to be in this country. In this city, only a few weeks ago, one of the most successful and largest meetings of the Photographic Society of Boston that was ever held, was drawn together by photographers being interested in witnessing a very successful lecture and demonstration of the working of the carbon process by Mr. Derham, at Allen and Rowell's.

"Messrs. Allen and Rowell have been successful workers in carbon for many years, and since 1873 have kept one operator, Mr. Derham, constantly employed at carbon

work, and on an average they must use up over two hundred rolls a year of tissue for their own business, besides what they sell to licencees. The display at the entrance to their studio on Winter Street is composed of carbon prints only, and they are now prepared to execute any and all orders from carte-de-visite up to life-size.

"I have printed life-size portraits in carbon in a direct solar printer, using one of Dallmeyer's 18 lenses, in ten minutes, by using a very strong bichromate solution, and from an intense negative.

"In my opinion, one of the principal causes of carbon not being more generally in use, is the apathy and ignorance of the public with regard to carbon, so few knowing anything about it. If it were in demand, Sarony, Kurtz, and others, would put men to work on the process who would get out good prints; but as long as the public are satisfied with silver prints, they are content to let carbon alone. I can name many who have worked it in this country, who have, and are making money by working the process, and whose reputation in the future for making prints which do not fade will be superior to those who adhere to the silver print.

"The majority of photographers who have commenced to experiment in carbon printing have not given it a fair test. They ought to study the nature of bichromate gelatine, so that in their own particular locality it can be successfully worked, for in different parts of the United States a different mode of working is necessary. I should advise all who wish to work carbon to thoroughly study Dr. Eder's prize article on 'The Reactions of Chromic Acid and Chromates upon Substances of Organic Origin, considered with Reference to their Uses in Photography.'

"No operator in carbon can be successful unless he well understands the 'behaviour of chromated gelatine with heat and moisture.'

"If the majority of your readers were to see some of the European journals of photography during the last twelve months, they would be posted with regard to the probability as to the extinction of the use of carbon now and in the future. Never was such scientific discussion brought to bear on the manufacture of albumen paper as is now on the manufacture of carbon tissue. The discussions during the last six months between Dr. Monckhoven and Mr. J. R. Johnson, and also Mr. J. R. Sawyer, of the Autotype Company, cannot help but educate the European photographer with regard to the durability of the colours used in the manufacture of pigment."

Notes and Queries.

MARINE PHOTOGRAPHS.

DEAR SIR,—In reply to "Marine" in "Notes and Queries" in the last issue of your valuable journal, I write to say that I shall be glad to supply him with prints from a number of negatives I took during a four or five years' residence at Ryde, I.W. They are instantaneous pictures, exposed by drop shutter, and represent chiefly the yachts racing during the Royal Squadron, Royal Victoria, and Royal Albert Regattas. As I have facilities here also for taking similar marine subjects, I would do others if required. If he will kindly communicate with me I shall be happy to let him see a specimen or two which, I think, he will be pleased with, for, although troublesome to obtain, the results afford me more pleasure than any other pictures I do. If you would like to see these, I can send them to your office for "Marine" to call and see.—I am, dear sir, yours faithfully, T. J. SCOTT.

4, St. Peter's Street, St. Helier's, Jersey, April 26th.

SIR,—Messrs. Symonds and Co., Marine Photographers, Portsmouth, would be able, in reply to "Marine's" enquiries in your "Notes and Queries," to supply him with photographs of ships, still life, and yachts, &c., in motion.

Portsmouth, April 26th.

PHOSPHORESCENT PHOTOGRAPHS.

WE introduce to our readers, this week, another interesting novelty, not difficult to produce. On another page, Mr. Woodbury describes his mode of producing phosphorescent photographs. The possibility of producing such pictures depends upon the property possessed by some substances of practically storing up light. That is, some substances when exposed to the sun's rays seem to absorb the light, and subsequently emit a phosphorescent light in the dark. To apply this principle to photography, the problem is to find a means of forming an image of particles of such a phosphorescent substance. Many years ago, we remember an ingenious photographer propounding the problem, "How can I form a photographic image in some phosphorescent body?" At that time, when nothing beyond the ordinary silver processes was known, the problem seemed to be insoluble. Now, more than one method probably exists. To Mr. Woodbury's inventive ingenuity we owe the one which has been tested, and is a practical success. The method he employs is known as the "dusting-on" process. It consists in coating a plate with a preparation of dextrine, honey, and bichromate of ammonia, which, exposed under a negative, becomes hardened, where it is subjected to the action of light, through the transparent parts of the negative, remaining tacky where it is protected from the action of light by the denser parts of the negative. After exposure under a negative, the film, as it will be seen, is tacky in the lights of the picture, but hard and dry where light has acted on the shadows. The lights are therefore adhesive and tacky, retaining any fine powder which is dusted in or rubbed into the moist surface. At this point comes in the essential novelty. The powder to be used must be a phosphorescent substance. One of the best known and available is sulphide of calcium; a powder of this substance is applied to the image formed on the adhesive film, and sticks to it in due gradation of the tackiness, as regulated by the action of light which passed through the negative. An image of sulphide of calcium is thus formed, which, the powder being nearly white, is scarcely visible by daylight, but if the image be submitted for a time to sunlight, or bright daylight, or brilliant artificial light, and then taken into the dark, presents a luminous picture, somewhat startling, indeed, in the case of a portrait.

A variety of substances possess this phosphorescent quality: sulphides of barium, calcium, and strontium displaying it in the most marked degree; fluor-spar, carbonate of lime, pearls, diamonds, phosphate of lime, arseniate of lime, and other substances, all showing in their degree this capacity of absorbing light and radiating

it in the dark. The Bologna stone, consisting of sulphide of barium, displays this property in a marked degree. The old Italian cobbler to whom tradition assigns the discovery of the property of this stone, and its use to astonish his friends and neighbours, prepared it by heating red hot with charcoal a piece of sulphate of baryta, found plentifully in the neighbourhood of Bologna. Sulphate of baryta made into a firm paste with gum, or with flour and water, and calcined, will produce the substance. It should be kept sealed in a stoppered bottle.

The phosphorescent property has been utilized in America for the production of luminous clock and watch faces, which readily show the hour in the dark. Professor Morton, in the *Scientific American*, points out the possibility of superseding gas or other incandescent substances as means of illumination by having the walls of a room treated with a phosphorescent substance, which might absorb sufficient light during the day to serve for illumination at night. Dr. Phipson points out that a white-washed cottage exposed during the day to strong sunlight sometimes shines at night with a brilliant phosphorescent light; pure lime or a mixture of lime and nitrate of lime possessing the property in question. The substance used in preparing luminous clock faces is sulphide of calcium, sometimes known as *Canton's phosphorus*, Canton having prepared it by heating a mixture of three parts of calcined oyster shells with one part of sulphur to an intense heat for an hour. It may also be formed by heating gypsum with charcoal. The most refrangible or actinic rays are most active in producing this phosphorescence, or fluorescence.

Mr. Woodbury, so far as we know, is the first to give this property a practical purpose in photography. He applies the sulphide of calcium in powder to the image formed by light on a surface possessing an elective degree of tackiness, and the image being so formed and submitted to the action of sunlight, or even a good artificial light, presents a luminous picture in the dark. Used with judgment, such portraits may be found very interesting; whilst, perhaps, nothing could be more ghastly than the unexpected presentation of such a portrait of a deceased friend.

To those of our readers who may desire to study the question of phosphorescence generally in connection with this subject, we cannot recommend any better assistance than the very interesting work on "Phosphorescence, or the Emission of Light by Minerals, Plants, and Man," issued by Dr. Phipson a few years ago.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY AS A MEANS OF POPULAR INSTRUCTION.

WHEN the art of printing was first invented the influence it was destined to exercise on civilization and on the diffusion of learning was scarcely suspected. The gleams with which Caxton,* Guttenberg, and Laurence Coster enlightened the world are even now giving out their heat; the waves of knowledge which their books have produced have never encountered a dam strong enough to prevent them from forming the intellectual ocean on which floats our civilization of to-day. Photography, as a propelling force, is not far from performing a similar part; wherever it penetrates, there it irradiates, as if to prove that owing its origin to light, it is called upon to diffuse light. The onward march of our art will now never be arrested. In our hours of relaxation it forms one of the most delightful of our recreations. In the family circle photographs refine our leisure, and give rise to countless emotions by recalling to our memories departed relatives and absent friends. The recluse in his chimney corner, by the aid of his album, surrounds himself with friends, and peoples the recesses of his garret. In many a social party a lasting friendship

* I give Caxton the first place, because every day it becomes more certain that your countryman, if not the first to discover moveable type, at least did so independently of others.

is established, for a collection of portraits of this kind is apt to give occasion to remarks on the good qualities of one who is no longer separated from us when we can count the number of miles that he is distant. A photographic portrait, also, will often lead us to speak of the merits of some remarkable man of our time. In art, again, as well as in science, we recognize the value of photography; it displays nature to the artist, and reveals her secrets to the philosopher, while the student has no more powerful aid. In all the departments of the public service our art is made use of. It saves both time and money, for what it reproduces is true. The eyes of the objective cannot be deceived, as are so often those of the draughtsman.

It is, therefore, no wonder that printing, though we thought it already strong enough to do without any extraneous assistance, should borrow from photography many virtues which were still wanting to render its efficacy complete. M. Leon Vidal, my respected colleague, has recently abundantly demonstrated this in a lecture, much appreciated and applauded, which he delivered at the late congress of learned societies at the Sorbonne. The time will soon arrive when an illustrated work not produced by some heliographic process will be hardly deemed worthy of that title. A work, young as it has always been considered on its publication, will henceforth, thanks to photography, be still more rejuvenated, and if it makes its appearance without photographs it will be treated as an old one born a second time. This is almost equal to the art of the magician!

We shall now never be astonished if every day brings some fresh proof of the part that our art is capable of playing in popularizing learning in our art. Only yesterday there has sprung into existence in this country a project which is destined to make rapid progress. It is proposed to organize public courses of lessons, illustrated by photographs, in all the smaller towns and villages, not only in the elementary schools, but for the general public, in the common halls, or even in the market places. There will be thus given in the open air courses of instruction whose benefits will be diffused among the masses (just as a number of commercial houses, to attract customers, advertise in our sheets) by means of illuminated transparencies before the eyes of admiring crowds. The plan on which it is proposed to carry this project into effect will be as follows:—Each locality will have to provide a projection apparatus. This may be, in an important and wealthy centre, the electric light, or in the case of a less ambitious place, some other illuminating apparatus more easy and economical to work. The authorities of the locality will receive from the Government a number of photographic pictures adapted for projection, or when the number of pictures thus offered to it is too small to satisfy its legitimate aspirations, it will be allowed to purchase others at its own expense. At a fixed time during class hours the schoolmaster will give lessons, illustrated by means of these pictures and the projection apparatus, in geography, mechanics, natural history, &c.; at another time, either he, or professors appointed specially for the purpose, will give lectures similarly illustrated to the parents of the children and those of his fellow-townsmen who may wish to take advantage of his instruction.

Lessons given in this way will not only be instructive, they will be amusing and interesting, for they will be of the nature of object-lessons, which are always the most easy to understand. The eye will merely have to look on the moving picture to acquire a knowledge of the country of which the principal views are exhibited, and thus a voyage may be made without leaving one's seat. The audience will be able to see agricultural machines and the new inventions that have been shown at the latest exhibition; the farmer may follow the descriptions of the most recent discoveries which he can, if he wishes, introduce into his business. By this means our rural population may be made acquainted with all the machines and im-

plements of production of our time—with the forms of animals of other countries, with model farms, with the best methods of manuring, with the creatures that live in the lakes, rivers, and seas, in the air, on the trees or the ground, with the old world and its former civilization, with the wonders of the day, with the portraits of celebrated men; and every one, while being amused, will take in a kind of knowledge from which he cannot fail to derive profit in his daily life. Those who are unable to read—and there are many such, though their number decreases every day—will be able to read as from an open book, from the screen on which one photographic picture is projected only to make way for another, each leaving on the mind deep traces which form the seed for an intellectual harvest.

This admirable scheme is just now under the consideration of the French Government, and, if it be carried out, it will certainly be not the least of its glories. Moreover, if doubters or dawdlers be charged with the execution of the work, other countries will certainly be in advance of us. Only a few days ago a foreign gentleman of the name of Levy arrived in Paris, to examine a projection apparatus ordered from Messrs. Moltini Brothers, the well-known makers, who are always ready to give the advantage of their experience and of their excellent instruments to those who have need of them for some useful object. It appears that the apparatus in question is the largest ever yet made, and that M. Levy intends to take it, together with a number of photographs of natural objects, to America, where he proposes to deliver a series of public lectures, and to introduce, at his own cost, the system of instruction which I have spoken of as likely to be undertaken in France by the Government. My best wishes for the success of his experiments accompany M. Levy. No doubt will be felt in England as to that success, nor will my wishes fail to find an echo there—England, that classic land of lectures and conferences, which has done so much by its powerful example to excite a taste for them in other countries.

It is always with a feeling of legitimate satisfaction that I bring into notice the valuable results of the applications of photography. Niepce and Daguerre probably never suspected, when they discovered the sun to be so true a draughtsman, that their invention would be a foundation on which would be raised so marvellous a superstructure. We can scarcely sufficiently acknowledge the services they have rendered to mankind, and in paying only a just tribute of admiration to their illustrious memory (in which they ought never to be separated), we are unable to give enough praise to the efforts of those who, in their turn, endeavour to learn from photography the lessons it so abundantly teaches. For this reason we ought to applaud with all our heart any attempts to diffuse a taste for photography by means of lectures and public courses of instruction, and I shall always feel it my duty to support, as far as I possibly can, men who, like M. Bardy, M. Davanne, and M. Leon Vidal, make it their aim to develop the scientific applications of our art.

I welcome with pleasure, in spite of their mutual jealousies of each other's position, the formation of new societies whose object it is to keep alive the sacred fire and to maintain the zeal of the photographic world. Such are the *Societe des Employes en Photographie*, which has recently published a report on the works of the profession exhibited at the late International Exhibition; the *Union Photographique de France*, which proposes to hold its first quarterly meeting on the 7th May next; the *Societe des Archives Photographiques, Historiques, et Monumentales*, which, although the oldest of these new societies, has shown so much spirit that, in spite of the bad weather, it successfully accomplished its second artistic and scientific excursion that had been announced for the 20th of this month (April). This excursion was to the full as great a success as the first one.

As being in connection with the same subject, I shall always follow with great interest the endeavours made in various quarters to promote the study of photography by organising its means of action. For instance, just at the present time it is reported that a project is on foot for the establishment of a special photographic branch in one of the ministerial departments in Paris. My sincere wishes for its speedy realisation accompany this project. To concentrate individual efforts and give them a collective force, is not only a want of our Government when it is a question of an art which constitutes the most valuable application of science of our age; it is more—we cannot all of us but desire, for the sake of the results obtained, that this art may be officially proclaimed to be worthy of an important place in the public service. K. VERSNAEYEN.

EPHEMERAL PHOTOGRAPHY.

BY WALTER E. WOODBURY.

IN the present day, when everyone is searching after permanency, the title of this article will seem out of place, therefore I had better explain that what I am about to describe is simply a pretty and interesting experiment (new, I believe), by which photographers may amuse their friends and lecturers their audiences.

The process is simple, and has this advantage: that the same piece of sensitized paper may, owing to its ephemeral nature, be used over and over again, and at the same time always retain its sensibility.

The material is the phosphorescent powder, sulphide of calcium obtained by calcining oyster shells and treating with sulphur. A sheet of paper is coated with this by covering with gum or varnish, and dusting the powder over it. If this paper is exposed for a few seconds to light under a positive, and then removed to a dark room, a luminous positive will be seen, lasting a longer or shorter time, according to the exposure given.

I have also produced phosphorescent portraits and views by the dusting-on process, substituting the powder for plumbago.

These experiments, although of little value scientifically, are interesting, and add to the uses that the phosphorescent properties of the sulphides have been put to. Given the same strides that electricity has made, it is perhaps possible that in fifty years to come, the study of phosphorescence may make equal advances, and photographs may be taken at night by the aid of the light that emanates from the walls of the studio.

The old story of the cucumbers and sunbeams, like many another fable, is becoming a reality in this era of advance in science.

IMPROVED DIPPER.

BY E. DOBSON.

I was for some years troubled with breaking of glass and porcelain dippers, to say nothing about the number of plates that slipped off the dipper; so I made one myself which I am pleased to say has never failed me; no matter in what position the dipper may be, the plate cannot leave it. I enclose a sketch from which any boy can make one. The one I made is of box-wood, and although I have worked it for over twelve months, it does not injure the bath.

Fig. 1 is the dipper of box-wood with three holes cut through No. 1, 2, and 3; from the bottom of these three holes, slots are to be cut in No. 1, as low as the top of the smallest plate to be used (mine is a 10 by 8 plate bath, but I use it for $\frac{1}{4}$ -plates). Slots from holes No. 2 and 3 must be cut so that when the piece, fig. 3, is put in the holes, it comes within half an inch of the bottom of the bath.

Fig. 2 is a piece of box-wood cut to shape, and bevelled outwards at bottom with a projecting piece at back; at the end of this piece it is cut like a button; this button is slipped

through the hole No. 1, and can then be slid up and down the dipper, and it does not matter what thickness the plate, it will hold it.

Fig. 3 is a piece cut with two button-like pieces which are slipped through holes No. 2 and 3. Although it seems rather complicated, so simple is it that one can almost be made in the time it takes to describe it.

A NEW DEPARTURE.

Mr. D. N. CARVALHO writes to *Anthony's Bulletin* as follows:—

“Since the inception of and production of the photographic image, the efforts of all seem to have lain in one direction, viz., to be able to obtain with a very short exposure a full-timed negative. Chemistry has been peered into, wonderful discoveries productive of varied results obtained; but still the desired goal of being able to work and use all one had to work with was as far off as ever, from the simple fact that there would be times when the chemicals would work slowly from other than natural causes.

“Working under a skylight, the room being painted a sort of brown, and which room the week previously had been of the ‘orthodox blue’ found in most of the studios throughout the country; working with the same instruments and under pretty nearly the same conditions. I noticed that it took less time to make a negative in the brown than it had done in the blue room. Here was food for thought. Was this so? and, if so, why? I then began a course of experimenting with the following wonderful results. Of the various colours of the spectrum the violet we find to be the most ‘actinic,’ and the yellow or orange ray the ‘non-actinic.’ Now take a clean winc-glass filled with some transparent blue liquid, place the glass on a clean sheet of white paper, permit a ray of light to pass through it, and you will find the shadow cast by it to be orange; likewise does a blue substance reflect orange, both being complementary to each other—so that a gallery painted blue reflected on the sitter orange, making it necessary to lengthen the exposure in order to overcome this non-actinic effect. The brown-painted gallery absorbed the light, to a great extent, leaving nothing but what entered through the skylight.

“It then occurred to me that, if I could find a colour to reflect a ‘violet,’ I might thus be able to use advantageously all the light. I found not only the above result in experimenting, but that of the three colours, blue, red, and yellow, or orange, each and every one reflected a combination of those remaining; thus, if blue reflected orange, orange in return complemented and reflected blue, red reflecting green, and green, red; then green + yellow reflects red + blue, or its equivalent, purple. The purple obtained, it was an easy task to obtain the ‘violet,’ which was produced, or rather reflected, from a colour resembling somewhat an orange pea green. I had my skylight room immediately coloured as near as possible to what I had attained, and here is what happened: where formerly it took from thirty to forty seconds to make a large $\frac{1}{4}$ head, by the ‘new departure’ fifteen seconds was more than enough, twelve seconds being ample time, and under very favourable circumstances six to eight seconds. But there is one trouble to overcome: things work so quickly that it is hard to control the light.

"Another feature in regard to this orange-green painted gallery: there is no complaint about the light being too strong for the sitters' eyes, green being, as is well known, the restoring colour. The reflection of this colour, violet, also renders the high lights more positive, and the shadows softer."

Correspondence.

PHOTOGRAPHIC PARADOX, ETC.

DEAR SIR,—Has not Mr. Murray gone rather beyond the general belief in supposing that the blue and violet rays are not required for gelatino-bromide plates? Some five years close experimenting in most of the dry processes published—and gelatino-bromide especially—during which I have tried all the "pizins" in the pharmacopeia as accelerators, preservatives, &c., &c., with the object of getting the most rapid dry process possible, has gone far to convince me that while, undoubtedly, the red end of the spectrum has a considerable effect upon gelatino-bromide, it is yet very sensitive to the rays at the other end, and I am by no means prepared to concede that it is relatively so much slower in proportion to wet work *at its best* as some people seem to imagine.

Perhaps you will allow me to thank Captain Ahney for his articles on the spectrum rays intercepted by the various coloured glasses and dyes.

Some years since, when I first discovered the extreme sensitiveness of gelatino-bromide with extended digestion before washing, as pointed out by me in your YEAR-BOOK, I had to discard the use of coloured glass, finding it almost useless, and I have ever since used dyes, finding a thick chrysoïdine varnish of the most service, sometimes using aurine, but, so far, not touching magenta. I shall now, I apprehend, be practically invulnerable to actinic light.—
Yours truly,
RICHARD PARR.

DRY PLATES AND THE CHROMOGRAPH.

SIR,—The attention of dealers is called to the above. In regard to the first, it is pretty well understood that the English claim and take the first rank as the makers and preparers of such articles, and it would be to their interest to make representations to the proper authorities connected with the Customs that an arrangement should be arrived at for the package of such prepared articles without the chance of their destruction by exposure to light. They should also, as dry plates are in increasing demand at home, have some security for their transit on parcel terms, without the risk of being opened or spoilt by Post Office officials. Amateurs are spread about in hundreds of out-of-the-way places only to be reached by post, so that dealers would consult their own interest by moving in the matter. Combined action, as in the recent case of the *Papyrograph*, &c., would do much for them. As your French Correspondent has given some valuable information in connection with the Chromograph, it might answer the purpose of some of the photographic dealers who use the pages of the NEWS to get an agency from the inventor of the Chromograph, as it would evidently, from its small cost and simplicity, be of much use to authors, artists, and antiquarians, and a great demand would probably come in from amateurs, school-teachers, and others who may require from thirty to forty copies of some particular note or outline sketch.—Yours, &c.,
THE OLD HAND.

BUILDING A STUDIO.

DEAR SIR,—Since writing to you, I have run over various clauses of the Metropolitan Building Act, and can see no way of fully meeting its requirements but by some such arrangement as you suggested; but I think if plans were

submitted to that or any of the provincial Boards before commencing, they would permit the erection of such a studio as I described in the YEAR-BOOK, provided the outer sheathing of roof, sides, and ends were made of galvanized iron, which can be obtained (corrugated) of various thicknesses in sheets six feet by two feet three inches.

I have run out one or two ways of putting up the frame of such a studio of angle or T-iron, and like it so much that if again erecting one I think I should use it; but on jotting down the number of holes to be drilled, and pieces to be bent and cut at the forge, it is painfully evident that no ordinary (photographic) amateur would tackle such a job, for which reason I think it is scarcely necessary to trouble you with fresh plans and details, and content myself with showing how, and at what cost, the wooden frame of the studio I described can be covered with corrugated galvanized iron, a sheet of which, 20-gauge (or decimal .035 of an inch) thick, six feet long by two feet three inches wide, weighs, as nearly as I can estimate it, about 23lb., and can be cut with a pair of tinsmith's shears (costing about 3s. 6d.) Six feet, however, will be found too short to cover one side of the roof, and rather than join it I would reduce the height of the ridge to nine feet, which I prefer to a higher roof provided it can be kept watertight (and this will be easy with such material); if the frame is put up and it be intended to substitute iron sheathing for wood, I would of course join the iron rather than alter the frame. The iron is to overlap at the joints three inches, and be riveted with quarter-inch rivets about three-eighths of an inch long, and it must be nailed to the framing with one inch rose-headed nails, and the heads puttied. The holes can easily be punched *in situ* with the joiners' punches, one-eighth of an inch for the nails, and quarter-inch for the rivet-holes, a lump of lead weighing five or six pounds being held behind the plates at the rivet-holes, using a heavy hammer (one pound and a quarter).

The roof sheets must be nailed on with a space of an inch between the opposite sides at the ridge, so that a strip of wood one inch square, twenty-four feet long, can be nailed on the ridge, to which must be nailed strips of the iron cut lengthways of the plate, one "curve" wide, the convex side uppermost, and the side, of course, overlapping. The roof-pieces will overhang about two inches at the eaves, and must be so arranged that the curves fit *into* those of the side sheets, making a close joint. Fifty-one sheets of iron will be required, weighing (say) ten and a-half hundredweight, and it can now be bought at about 26s per hundredweight, or less, say £13 13s., the cost of the studio being (say) 20 guineas, as follows:—Deduct from cost estimated for wood (£10 16s. 6d.) cost of floor board £3 18s., nails 3s. 2d., and asphaltic and brush 6s., leaving cost of framing £6 9s. 4d., to which add the cost of the iron, and (say) 3s. for nails and rivets—6 lbs. at 6d. An iron frame would add about £4 or £5 to the cost, besides a large amount of labour; and if any of your readers are inclined to incur this, I will send details, provided you think it worth while.—Yours truly,

RICHARD PARR.

Proceedings of Societies.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

THE ordinary monthly meeting of the above Society was held on Monday, the 7th inst., at the Market Tavern, Bradford, Mr. JOHN HOWARTH, President, in the chair.

After the confirmation of the minutes of the previous meeting,

A lantern exhibition was given by the PRESIDENT, ably assisted by Mr. W. T. BURROW, who, in an interesting manner, described the various pictures depicted upon the screen, at the same time criticising the quality of each transparency, most of

which were by the Woodburytype Company and by Ferrier, of Paris. At the close of the exhibition a very cordial vote of thanks was given to the two gentlemen for their highly interesting entertainment and gratuitous use of Mr. Howarth's scription.

Mr. BURROW thanked the ladies and members present for their kind attention and attendance.

Mr. HOWARTH also thanked them, and was pleased to see such a good attendance, which he thought augured well for the future success of the Society, and hoped it was only preliminary to many more such evenings together.

After some desultory conversation, the SECRETARY announced that Mr. Garrett had promised to read a paper at the May meeting, which would be the last indoor meeting for the present session.

The CHAIRMAN announced the meeting adjourned until Monday, the 5th May.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on Thursday evening, the 24th ult., at the Free Public Library, William Brown Street, Mr. J. H. T. ELLERBECK, Vice-President, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. E. ROBERTS showed a number of capital transparencies taken on gelatine plates, and in reply to inquiries, said that he prepared two ounces of emulsion by putting one and a-half ounce of water into a three-ounce bottle, dropping into that fourteen grains of bromide of ammonium, and when dissolved, putting in forty grains of Nelson's photographic gelatine, and dissolving by placing the bottle in hot water. He then dissolved twenty-two grains of nitrate of silver in half-an-ounce of water, and poured it into the gelatine. This made up the two ounces. After shaking up well and keeping warm (say 90°) for forty-eight hours, the emulsion was then filtered, and the plates coated. When the films were set, each plate was dipped for a few moments in cold water and set up to dry. The formula was much the same as what had been already published by Mr. C. Bennett, but washing the plate after coating simplified the making up of the emulsion, and though Mr. Roberts had only used the plates a week old, they were quite as perfect as any he had seen.

The President of the Manchester Photographic Society (Mr. C. ADIN) sent some capital portraits taken by the luxograph light for presentation to the album. Several of the portraits were recognized by the members, and considered excellent examples of the success of the light.

The Rev. H. J. PALMER then read a paper on "Notes of Comparative Experiments with Gelatine Emulsions" (in our next).

Some discussion followed, and objections were made to Mr. Palmer's statement as to the rapidity of some plates against others.

The SECRETARY said he found no difficulty in obtaining the requisite density in landscape negatives with Swan's plates, provided that the development was with ammonia, and not hurried. The prints he handed round were groups secured during rain in dull light, and views in sunshine, all taken with the same single view lens, exposure ten to fifteen seconds, and they were all that could be desired. The groups were of a wedding party, and though other plates had been used with four times the exposure and full aperture of a rapid lens, only failures were the result. He should recommend Swan's plates for such occasions, not only for their convenience and rapidity necessary in taking groups, but also as they did not give such great contrasts between the light dresses of the ladies to those of the gentlemen.

Mr. H. WOOD showed some views taken at Hale, to induce members to go there with their cameras.

Mr. W. B. ROBERTS exhibited a number of views of Trefew, &c., taken on gelatine plates after Mr. Houlgrave's formula.

Votes of thanks were passed to the Rev. H. J. Palmer, Mr. Adin, and to Mr. J. B. Payne, of Manchester, who had forwarded for distribution among the members a number of his very handy developing instructions for the different photographic dry plates.

An excursion was announced to Bromborough on the 10th instant, and the meeting was then adjourned to the 29th instant.

PHOTOGRAPHIC SOCIETY OF FRANCE.

At the meeting of the 7th March, M. PELIGOT, Member of the Institute, in the chair, Mr. WOODBURY was present as guest.

After the admission of new members, the SECRETARY drew

attention to a circular letter signed by M. G. C. Levey, announcing the opening of an international exhibition of arts and manufactures at Melbourne, Australia, on the 1st October, 1880. Hopes were expressed that French photographers would be well represented on this occasion.

M. PERRET DE CHAUMEUX read some extracts from the foreign and home scientific journals. In the *Moniteur Scientifique* there was described a method of making stoppers of caoutchouc. To cut out these stoppers it is better to keep the knife moistened with a solution of potassium carbonate, instead of caustic soda or potash as is generally done. By keeping the caoutchouc pressed firmly on a piece of cork until the elastic stopper is completely cut out, its diameter will be prevented from contracting. An article in the *Photographische Correspondenz* recommended the use of sheep's wool instead of cotton for filtering collodion. The neck of the funnel must be fitted as loosely as possible, when the woollen fibres will be found not to be liable to stick together, so that filtration could be continued with the same substance for a great length of time.

M. DAVANNE observed that M. Ferrier had for more than fifteen years successfully used wool for filtering, not only collodion, but also albumen and gelatine; he employs the common wool of commerce freed from grease, and to remove the last trace of fatty matter he dips it in a little ether.

M. PECTOR also stated that he had adopted this plan of M. Ferrier, and with the best results.

A discussion arose upon a translation being read of Captain Abney's paper on gelatine emulsions which appeared in our issue of the 21st February last. Fears were expressed that drying the film by immersion in alcohol, as recommended by the author, would cause the gelatine to wrinkle, as some years ago M. Placet had taken out a patent for producing by this means a grain in plates for engraving.

The PRESIDENT also remarked that the rarity of the salt would prevent potassium nitrite from being extensively used.

M. BARDY objected that the saltpetre left in the emulsion is not the cause of its keeping; he had himself preserved emulsified gelatine for more than a year after having completely dialysed it; but the results obtained were precisely the same as those described by Captain Abney.

M. DAVANNE exhibited Mr. Woodbury's new actinometer, which has already been described in our columns (see PHOTOGRAPHIC NEWS for 14th March, page 127).

Mr. WOODBURY also exhibited some specimens of paper filigreed by means of photography; but as he did not explain his method of making them, it is supposed to be the same as that which he patented in 1867.

A paper by M. MAGNY was read describing a method of removing negatives from glass plates. He first mentioned the different processes of the same kind that had been previously published, and pointed out their defects. His own method consists in removing the negative from its glass support to a sheet of gelatine by means of a transfer paper. The latter is prepared by dissolving over the water bath—

Gum-arabic	25 grammes
Water	100 c.c.

To which—

Gelatine	0.5 gramme
Glycerinc	3 c.c.

have been added to render the gum less brittle. After this solution is filtered, a sheet of paper is coated with it, either by floating the paper on it, or by applying it to the latter with a brush. Great care must be taken to avoid air-bubbles (if they form they must be removed with the finger), and the plate is then hung up by a couple of pins to dry. The negative that is to be detached should have been taken on a glass plate well polished with talc; this plate is plunged in water, a piece of the transfer paper of the same size as the plate is floated over it, and both are then lifted out together, carefully drained, and placed between two sheets of blotting-paper; upon these is stretched an india-rubber cloth, and the whole is then gone over, lightly but regularly, with a wet squeegee. The excess of gum is then drained off, and the plate is next placed for a few minutes under some plain surface, weighted, so as to produce pressure. When the weight is removed, the paper is cut round at a distance of from two to three mm. from the edge of the plate, and, after being sponged lightly with a wet sponge, it can be drawn smoothly and regularly off, bringing the negative with it. Now to transfer this negative a second time, a sheet of commercial gelatine must first be immersed in water containing from three to four per cent. of

glycerine, and allowed to soften; it must have been cut to a size about one centim. larger all round than the glass plate which is to serve as its support. This glass plate has previously been coated with plain collodion, and afterwards washed and dried; it is slipped underneath the gelatine sheet, and both are lifted out together as in the former operation. It is then placed on a stand and levelled by means of screws, and the excess of water as well as all bubbles are squeezed out at the edges by means of a flat brush moistened in water. As much water as the gelatine will hold is now dropped on it from the brush, and the paper negative is drawn over it, commencing at the lower part and passing regularly to the top, so as to remove all excess of water. The glass plate is now raised, and, as in the preceding operation, placed between two sheets of blotting-paper underneath an india-rubber cloth, and the whole is then gone over with the wet squeegee. By placing it in a printing-frame until the gelatine has set, the overlapping portions of the latter can be turned back over the edges of the plate; the paper is then allowed to dry, care being taken not to hasten the desiccation by raising the temperature, or the gelatine will be liable to split off the plate before the drying is complete. The plate is now plunged in a pan of cold water, and after two or three minutes the paper can be raised and easily drawn off, leaving the negative on the gelatine. Lastly, when the sheet of gelatine is quite dry, it is cut round at a distance of from one to two mm. from the edge of the plate, when it separates without difficulty. A negative treated in this way can be retouched with the greatest facility.

M. BARDY read a paper on the various substances that were proposed as substitutes for yellow glass in lighting photographic laboratories, and investigated their comparative value for this purpose. His paper was illustrated by a series of demonstrations of the spectra of these substances projected on the screen by the oxy-hydrogen lamp. The demonstrations were made by M. Laurent with an apparatus of his own construction, which he had been good enough to place at the disposal of the Society.

PHOTOGRAPHIC SOCIETY OF BERLIN.

AN ordinary meeting of this Society was held on the 6th March, Herr C. BRASCH in the chair.

The report was read of the committee to whom had been referred the examination of Voightlander's Euryscope, and the investigation of the value of the process by which a current of galvanic electricity is made to pass diagonally across a sensitized plate during the exposure. On the first point the committee reported that they had compared the Euryscope with a Portrait Triplet Objective by Busch, and from that it worked about one-third slower, but gave much sharper definition and greater depth. The angle of aperture without diaphragm is only 15° ; on the other hand, the chemical focus is all that could be desired. As regards the action of an electrical current on an exposed plate, the results obtained by experiment were purely negative; the committee, therefore, hardly felt in a position to express a decided opinion on the merits of the process. The current, which was excited by a single element only, was so weak that some doubt arose whether inserting the plate had not increased the resistance to such an extent as to interrupt it altogether. For this reason the committee propose to renew their experiments under more favourable circumstances.

Dr. JESSEN brought to the notice of the meeting the glazed starch of Herr W. Kruse, of Stralsund, which he recommended as a most excellent preparation for the use of photographers. He also submitted a collection of collotypes by Messrs. Strumper and Co., of Hamburg. Apart from the careful execution and delicate appearance of the prints, the whole collection had a peculiar interest of its own, as offering almost an historical view of the collotype process.

Dr. STOLZE observed that in some of these prints the high relief had been considerably crushed, a mishap very difficult to avoid in collotypes. He also pointed out the existence of white lines, which he attributed to defects in the rollers.

Herr T. JOOR took advantage of the opportunity to make some remarks on the manipulations required in the collotype process. Contrary to ordinary photographic processes, in which the chief difficulties have been overcome when the negative is completed, these difficulties show themselves only in the collotype process in the preparation of the printing plates, and in the printing itself. Very often small spots appear on collotype plates, which are caused by small air-bells in the gelatine layer while in a fluid state; to get rid of these bells occasions great

trouble and annoyance. Great attention should be paid to the temperature in drying, which ought to be maintained constant at 45° R.

Herr A. ORR sent several specimens of carbon printing for exhibition at the meeting, illustrating the possibility of producing by the carbon process all the different kinds of drawing in chalk, Indian ink, pencil, &c. Some of these he presented to the Society for the portfolio.

At the next meeting of the Society, on the 20th of March, the chair was again occupied by the President, Herr C. BRASCH.

Dr. STOLZE was called on to give the continuation of his paper on his "Photographic Experiences of Travel in Persia." This consisted principally of an interesting account of the dangers and trouble accompanying the transport of chemicals and apparatus in a country like Persia, where a good road is an unknown quantity. Especial difficulty was met with in the carriage of volatile fluids like ether: when he first came to Persia, the speaker, on arriving at his place of destination, often found his bottles of sulphuric ether quite empty. Dr. Stolze recommends, as the only reliable luting for bottles, a mixture of sulphur and ground brick, which is melted, and in which the necks of the bottles, previously well corked, are then dipped. As regards landscape photography, he mentioned the interesting fact that in countries so near the equator as Persia, it is often advisable to work against the sun, and not under it, as is generally done at home. Employing the latter method, the almost vertical shadows would render the pictures very monotonous; but if taken against the sun contrast would—at least, to some extent—be secured. For the objectives to be used Dr. Stolze recommends the Pantoscope and Steinheil's achromatic combination whose anterior lens has been removed; with the Pantoscope and a very small diaphragm he had taken on an emulsion plate in the space of ten seconds negatives showing perfect depth and penetration.

On the subject of luting for bottles, Herr KARDATZ alluded to his own experiences in China, where he had found an india-rubber capsule to act perfectly. Dr. Stolze rejoined that the circumstances were quite different: Herr Kardatz's bottles were during the whole journey packed in the cool hold of a ship, and were first opened in China, where the temperature is comparatively low. Under a great heat the india-rubber corks would melt and spoil the contents of the bottles. It is well known that ebonite pans are in hot climates a standing danger for the silver bath. The only reliable means of stoppering bottles was the English method, which consists of a glass plate ground true.

Dr. JESSEN believed that plaster of Paris stirred into a solution of gum produced a perfectly air-tight luting.

Herr E. DUBY presented to the Society, in the name of Messrs. A. Braun and Co., a highly valuable collection of carbon prints. These prints are a proof of the pains taken by the house of Braun to maintain its position in the field of carbon photography; they are distinguished for great depth, sharp definition, and soft gradation. The same gentleman also exhibited a series of transparent positives by Herr F. Wilde, of Gorlitz, produced by his new process. An albumenized plate is coated with a special collodion containing silver; this is printed under a negative until a thoroughly over-exposed print is obtained. Without any intermediate washing, the plate is then placed in the fixing bath and well rinsed. The details of the process the speaker was unable to give, as they are kept secret by Herr Wilde; but several members present expressed an opinion that they depended on the formation of a collodio-chloride of silver, more especially as on some of the positives traces of gilding were discernible.

The meeting came to the conclusion that the new process is capable of great things, provided the necessary operations be carried out neatly and accurately, and carried a unanimous vote of thanks to Herr Wilde for his very interesting exposition.

Talk in the Studio.

INSTANTANEOUS DRY PLATES.—We have been favoured by Messrs. Wratten and Wainwright with some marvellous examples of the work of the gelatine emulsion plates, consisting of boat race scenes, in which the river and its banks, crowded with moving figures and craft of all kinds, from the slender and swift outrigger, to the massive steamboats, are wonderfully depicted in motion. Fine natural clouds, produced with the same exposure on the same plate, give pictorial value to the photographs, which are very excellent and marvellous.

THE LATE MR. W. PETTER.—On the 3rd inst. died Mr. William Petter, who was traveller for the house of Atkinson, Liverpool, over twenty years, at his residence, 129, Kensington, Liverpool, at the comparatively early age of fifty-five, after a long and severe illness. He will be remembered by many photographers throughout the kingdom as a courteous, and, at the same time, smart business man, and as one of the earliest of a now numerous class of photographic travellers on the road, and was esteemed and respected by all with whom he came in contact.

MOUNTING CHROMOTYPES.—*Autotype Notes* says: "Mr. Hawke, of Plymouth, has sent us some most admirable Chromotypes, very ingeniously treated, and very artistic in their effect. The negatives are masked square, oval, or with round corners, and printed so as to leave a white border, developed on glass in the usual way, the transfer paper applied as usual, and an extra sheet placed upon the plate so that the picture can be stripped as a thin card; when dry the prints are trimmed in a card-board cutting-machine to about the size that ordinary cartes are trimmed, they are then mounted by the extreme edges only with Russian glue, and placed under light pressure for a few moments. This mode is singularly effective, does away with all the trouble of double printing, allows the name of the artist to appear below the photograph, and, when pressed out as cameos, make very attractive pictures."

CONTINUOUS MEASUREMENT OF DAYLIGHT.—It is greatly to be desired that a good and simple method may be found of recording and measuring with some accuracy the variations of daylight throughout the day. This would render the weather record more complete, and it has an important special bearing on plant physiology. An attempt of the kind has lately been made by a German, Herr Kreusler, who has had made for him, by Liebertz, in Bonn, an apparatus with the following arrangement. It consists of a drum fixed with its axis in the plane of the meridian, and adjustable so as to be at right angles to the sun's rays. This drum has its border divided into 24 hours, 12 noon, and 12 midnight being in the meridian plane. A strip of paper, sensitized with solution of bichromate of potassium, and having divisions which correspond to those on the drum, is placed round this. A second drum closely surrounds the first, and is turned by clockwork (from which it can be detached) once in 24 hours, in the direction of the sun's apparent course. This second drum has a slit for admitting light to the paper; its width is such that any point on the paper is exposed 20 seconds as the slit passes over. The whole apparatus is placed in the open air under a glass bell jar. Its arrangement gives little trouble; the paper strip has merely to be placed in its position at night or under artificial shade (to avoid colouration) and the outer drum slid over and so attached to the rotating axis that the "insolation slit" is opposite the hour then present. The slit then begins to move round the inner drum correspondingly to the sun's course. The impressed slip, when removed in the evening, may be "fixed" by shortly dipping in water and drying between blotting-paper, or it may not, being quickly read; it shows a mostly continuous succession of bands of various shades of black, or rather brown. For comparison, Herr Kreusler made a scale of 10 degrees of darkening, exposing strips of the paper a given time under different angles of incidence of light. Bands of the experimental strip that appear homogeneous are now measured with reference to breadth (minutes and seconds) and intensity (by comparison with the scale), and the sum of the products of those quantities is taken as a measure of the action of light rays falling on the instrument in a given time. The results are considered highly satisfactory. —*Times*.

To Correspondents.

H. H. PHOTOGRAPHER.—It is quite certain that you must have failed in carrying out the instructions at some point; but we are sorry that we cannot tell you where. If you faithfully work out a formula which has given successful results to others, it would give you the same success. Only failure at some point could cause failure. The rapid gelatine process doubtless requires care at every stage, but at which stage you would be most likely to fail it is impossible to say. If you have succeeded in developing commercial rapid gelatine plates, it is not likely that your failure is in the development, but must be in the preparation. If there is fog you would generally see some trace of the image through the fog. 2. As we understand, none. 3. We should use common water, finally rinsing with distilled water.

A. Z.—The lens you have will serve for most purposes. For street scenes with moving figures, a lens of the compound or portrait combination will often be found desirable. We prefer the first-named maker. Compound stereographic lenses are suitable for street scenes and other instantaneous work, and for portraits.

J. S.—Various methods of albumenizing glasses have been described. We think the simplest and best is that in which the albumen solution is applied with a Blanchard brush, made by tying a piece of swan's-down cotton over the end of a stout strip of glass. An ounce of albumen in a pint of water, well beaten together, will serve. Some operators prefer it a little stronger, and use half the quantity of water.

A COMBINATION PRINTER.—Lane's Combination Printing Frame is manufactured and sold by Messrs. Maull and Fox, Cheapside.

SOUTH DEVON.—We presume they are similar, if not precisely the same; probably, both prepared by the same formula.

DIONORUS.—If you read Mr. Bennett's paper on gelatine plates, in our last volume, p. 511, you will find he describes the precise effect of keeping the emulsion. It is very easy to keep the dried gelatine pellicle ready for making just as much emulsion as you may wish to use. But there is change taking place in the emulsion. Mr. Cooper and various other experimentalists have given their experience in this direction.

J. R. D.—The proportion of pyroxyline for negative collodion must depend on the quality of the pyroxyline. About 4 or 5 grains form an average proportion. But we have used pyroxyline of which 3 grains made a thick collodion, and we have one in which 10 grains gave a limpid collodion. A powdery sample made at a high temperature will often give a good collodion with 6 or 7 grains. We prefer about equal parts of ether and alcohol.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR JANUARY

BY WILLIAM HENRY WATSON, F.C.S., F.M.S.

Observations taken at Braystones, near Whitehaven, 36 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE IN THE SHADE.			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1	—	—	—	35°	42°	35°	Fair, but windy and cloudy
2	29-67	29-75	29-70	25	33	31	Fair but cloudy. Rather windy
3	29-47	29-39	29-48	34	35	25-5	Fair, generally bright
4	29-57	29-57	29-87	33	33	33	Fair, clear, and sunny

PHOTOGRAPHY IN AND OUT OF THE STUDIO.
THE WORK OF SIR G. AIRY AND MR. GLAISHER AT GREENWICH—DR. HENRY DRAPER'S RECENT RESULTS—LEGISLATORS AND THE ELECTRIC LIGHT.

The Work of Sir G. Airy and Mr. Glaisher at Greenwich.—

A valuable publication has recently emanated from the Royal Observatory at Greenwich. It is a "Reduction of Twenty Years' Photographic Records of the Barometer and Dry and Wet Bulb Thermometers," and "Twenty-Seven Years' Observations of the Earth Thermometers, made at the Royal Observatory at Greenwich." The work has been published under the direction of the Astronomer-Royal, but, as our readers are well aware, a very large section of the labour has been performed by the esteemed president of the Photographic Society, Mr. James Glaisher, F.R.S., whose name as a meteorologist is a household word. Mr. Glaisher, who has but recently severed his connection with the Royal Observatory at Greenwich, where for many years he was superintendent of the Magnetic and Meteorological Section, has never received fair credit for the long years of patient work he has performed in connection with weather knowledge. To say nothing of his perilous ascents into the clouds, repeated not once or twice, but several scores of times, in one of which he attained to a height more lofty than that of any other human being, while in another he was so favoured that he beheld the full breadth of England stretched map-like below him, from Lowestoft on the one hand to the coast of Wales on the other—to say nothing, we repeat, of the valuable records made at these extreme altitudes, Mr. Glaisher's scientific work in the region of meteorology is such as must secure the admiration of every thoughtful man. It is a pity, therefore, seeing that the work done in the "Reduction" in question, for so many years past, is to a great extent the fruits of Mr. Glaisher's labours, that the Astronomer-Royal did not put his colleague's name more prominently forward. Of course, a head of department, in full power, like the Astronomer-Royal, can do pretty well as he pleases, either in ignoring, or putting prominently forward, the work of those who are associated as colleagues or as assistants; but for the very reason that his power is so great, we expect from him, perhaps, a little more than justice might call for. Mr. Glaisher, as a meteorologist, stands second to none in this country, and it is very certain that the announcement of his name in connection with any report or statement at once causes the same to be revived with greater confidence. It is not so long since that Mr. Glaisher explained to the Photographic Society the various uses to which photography is now put as a recorder at the Royal Observatory, and the "Reduction" is an embodiment of results secured in the manner the President then described. At that time, about five years or six years ago, there were no means at Greenwich for the registration of astronomical phenomena, but only of those connected with the magnetical and meteorological observing instruments. The motions of the declination, horizontal force, and vertical force magnets are all registered by photography. The position that a declination magnet assumes is termed the magnet meridian, and to register any change that may take place, this is compared with another, the astronomical meridian. Optical observations were formerly made at Greenwich of these instruments, and the consequence was, that skilled watchers were necessary day and night to look after them; now all such dreary work is at an end, and the duties undertaken by a never-napping photographic apparatus. A mirror arrangement is employed, and a pencil of light is thrown by its means from the moving magnet upon sensitive paper. The sensitive paper is put upon a cylinder that slowly revolves, and the beam of light traces a line upon the paper, which is the more wavy the more frequent are the magnetic disturbances of the earth. A marker or pencil, at the end of the suspended magnet bar, would be open to the objection of seriously impeding the

action of the moving magnet; a tiny mirror to reflect light does not do this. The electric condition of the earth from time to time is also written down by photography, every electric pulsation being recorded, and, as we have already intimated, the reading of the barometer, as also of dry and wet bulb thermometers, are registered in the same manner. The sensitive paper employed at Greenwich for these records is prepared by a modification of the calotype process, the impress of the light not being strong enough for an ordinary chloride of silver, such as presented by albumenized paper sensitized after the usual fashion. When the cylinder supporting the paper has completely revolved, the paper is stripped and the image developed. The process answers its purpose tolerably well, no doubt, but, taking into consideration the strides made by photography during the past few years, we think the Royal Observatory at Greenwich would do well to consider whether it might not now be improved upon, and the records impressed with still more sharpness and delicacy.

Dr. Henry Draper's Recent Results.—It is announced that Dr. Henry Draper, of New York, whose photographic work in connection with the spectrum is so well known, intends to visit this country during the summer. Dr. Draper, it may be remembered, discovered about a year ago unmistakable evidence of oxygen in the sun, through the medium of the camera; and although at the time there was a good deal of cavilling over the proofs he adduced, they were far too convincing to be gainsaid. Dr. Draper's critics, however, have had one good effect: they have caused the investigator to study the subject still further, and the result is further photographs upon a much larger scale, that bear out all previous evidence. The lines are shown with even more clearness in this second series, and henceforth there can be no excuse at all for doubting Dr. Henry Draper's discovery. Possibly our learned societies may feel inclined, after the scepticism expressed, to make the *amende honorable* to Dr. Draper when he honours us with his presence.

Legislators and the Electric Light.—We can hardly see what good can come of the Parliamentary Committee on electric lighting. If the electric light is good, whether for the illumination of streets and squares, or for private dwellings, any number of members of Parliament are hardly likely to influence the result. It is of little use, surely, to call up experts, or rather those who imagine themselves to be such, and to ask them whether they consider Mr. Edison is likely to invent anything useful, or questions of a similar character; nor do we think the catachising of inventors upon the advantages of their own machines is likely to prove much more than would the questioning of cobblers upon the merits of leather. The latter craftsmen could not be more eager to assure us that there was nothing like leather, than some of the gentlemen have spoken as to the merits of electric illumination. Dr. Siemens quotes an example—of which we should like to hear more, by the way—of a collision having been averted by the use of an electric light on board one of his own vessels. An approaching craft had neared to within a very short distance, and if it had not seen the electric light, and had been seen by those exhibiting the latter, there must have been a collision. The Board of Trade, he told the Committee, forbade the use of electric lights in ships under ordinary circumstances; but Dr. Siemens did not appear to know why. The reason is that ships shall not be mistaken for lighthouses, and the Board of Trade could, if desired, point to several instances in which collisions had actually occurred from such mistakes. Indeed, the incident to which Dr. Siemens himself refers may have been due to the circumstances of the approaching vessel imagining that the bright light on the Siemens' Ship was stationary, and not rapidly coming towards them. But, in any case, we can hardly see what good a Parliamentary Committee can do by examining persons more or less interested in inventions. If electric illumination is ever to be so improved as to come into general use in our houses or squares, the matter will not be brought about one moment sooner or later by the sitting of a committee of legislators of the country.

Correspondence.

COLOUR FOR INSIDE STUDIO.

DEAR SIR,—On reading the article intitled "A New Departure," in last week's *NEWS*, I was strongly reminded of a somewhat strange experience I had some years ago, but which in the light of the new theory is no longer strange.

The studio I occupied at that time was coloured a dark bluish-grey or lead colour, which had the effect of making the place look very dark and gloomy, the room being large, with considerable wall space. To overcome this, I had it repainted, the woodwork of the skylight and side light being painted a pure white, the walls and all other woodwork a light sage green, the cornices and mouldings being a slightly different colour. The change had the effect of making the room look bright and cheerful, and at the same time easy and pleasant to the eye. Pictures taken in the room before the change were somewhat hard and wanting in detail in the shadows if the exposures were not very full indeed. My surprise was therefore very great, on commencing work, to find the exposure much shorter, and, in fact, the pictures in every way improved. It never occurred to me that the green could have anything to do with the change, as I had selected it in the belief that the light reflected from it would be the same in quantity and quality as from the grey. The only reason for the change I could think of was the sashes being painted white, and the glass cleaned. This could not have been the cause, as no special attention was afterwards paid to the windows, and still the same results continued to be obtained until I left the place, being compelled to do so from ill health. I feel so sure that the green was the cause of the improvement, that I intend to colour my present studio in the same manner at the earliest opportunity. When I have done so, I will report the result.—I remain, yours truly,

A. BORLAND.

RAPID DRY PLATES FOR THE STUDIO.

DEAR SIR,—I should like to say a word of encouragement to all photographers who contemplate working the rapid gelatino-bromide dry process in their studios, as I know many are in great doubt what they should do. I believe it to be the process of the immediate future, and all who have not yet contemplated making any change from the old style ought certainly to consider the matter carefully if they wish to keep ahead.

In the first place, making the plates is such a simple matter, that a boy of ordinary intelligence can turn out enough in a day or two for a week's large business, having been once shown the way, and I think it much better for photographers to prepare their own whenever possible, although it is very convenient to be able to purchase thoroughly reliable plates; but that is just the point. We used some dozens of commercial plates, obtaining but very few fairly successful negatives, before determining to prepare our own.

Having worked out a process from the beginning, improving and simplifying all details, from the emulsion making to the developing of the negative, we are now in possession of a system of work from which nothing would induce us to return to wet collodion. The cost is not one-fourth of the old process, and the results are infinitely superior. Head-rests are banished from the studio, as well as the photographic smell which hangs about whenever collodion is used. Exposures in the glass-room are from a quarter of a second to one or two seconds, and the negative is ready for fixing in about half a minute after applying the developer.

Half plates, whole plates, and 12 by 10 are our regular working sizes—15 by 12 and 20 by 16 often—and we have no more difficulty with the larger sizes than with the small, and are certain in all cases of securing negatives of the highest quality, and printing as quickly as collodion.

Collodion has been a good old servant, and I for one have a great respect for him still; but he will as surely have to go before the gelatino-bromide process as the Daguerreotype did before him, and as the old mail coaches before the locomotive.—I remain, dear sir, yours, &c.,

W. H. NELSON.
Twickenham S. IV.

ON THE CONTINUATING ACTION OF LIGHT IN CARBON PRINTING.

BY E. W. FOXLEE.*

In the early days of the carbon process operators were often surprised to find upon development that their prints were much darker than they anticipated, until at last it was noticed that the longer the prints were kept between exposure and development the darker they became. The first to direct public attention to this matter was, I think, Lieutenant Abney, who read a paper on the subject before the Photographic Society, in 1872, in which he proved that the action once set up by light continued in darkness. At that time, and since, several have denied that any such action takes place; but this I can only attribute to limited experience or want of perception, as it is almost impossible to work the carbon process to any extent without being convinced of it, especially during hot and damp weather.

At the June, 1877, meeting of the Photographic Society of Great Britain, Mr. J. R. Sawyer again brought the matter forward, and read an excellent paper which he illustrated with some well-chosen examples, which proved incontestably that, not only did this action exist, but that it proceeded much more rapidly when the insolated tissue was freely exposed to the air than when protected from its influence. Through the kindness of that gentleman I am enabled to exhibit those specimens this evening, and I cannot do better than read an extract from his paper which will explain them in much better language than I could employ, and will at the same time serve to introduce my own experiments in this direction. Mr. Sawyer says:—

"What I wished to call your attention more especially to this evening, is the change that gradually takes place after the exposure of sensitive tissue for a very brief space to the action of light. We will take for example (say) a negative which, with a given tissue, requires an exposure of six tints. If we take several pieces of this tissue, and expose them one after the other for a very brief period upon a negative—say for *one* tint—we shall have a series of pictures which would be considered very much under-exposed, and if we develop one of these soon after its exposure to the light, we find, of course, that it is very much under-exposed, and, as a picture, worthless. We find that it is only in the very deepest shadows we get any vigour; that the half-tones will not hold; that they wash away, and the whole is simply worthless.

"Now let us cut our other pieces into two portions, distinguishing them by a letter on one portion, as well as the numbers. No. 1 we have developed, and we know exactly what effect is produced by the brief exposure to light; having cut the other portions in halves, let us distinguish them as No. 2, 2A, 3, 3A, and so on. Put those pieces distinguished by a number into a tin case carefully sealed from the light, and, as far as possible, from the atmosphere; put these pieces distinguished by a number and a letter into (say) an ordinary drawer. We thus create separate conditions—one series being kept from the light, and to a considerable extent from the atmosphere; the other being kept from light, but in contact with the air, and consequently to a great extent influenced by changes of temperature of hygrometric conditions.

"To continue our experiment; let us day after day develop one of the exposed prints, of course developing

* Read before the South London Photographic Society.

together the halves that belong to each other, and the results will be eminently instructive. We shall find that day by day the action of the light will be continued—not an universal fogging and decomposition over the whole of the surface, but every gradation of light and shade preserving its proper balance, until at last a point is reached when the picture is as good as possible; that is to say, a photograph in pigmented tissue has been produced by allowing the light to act upon it for only one-sixth of the time supposed to be necessary, the remainder being due to the continuation of the light's action, when the picture is no longer under its direct influence. But it must not be forgotten that our pieces of exposed tissues have been kept under slightly different conditions, both protected from the action of the light, but only one specially protected from the action of the external air. The one protected from the action of both light and air reaches its proper gradation of light and shade much more slowly than the one protected from the light only, showing that other elements than that of the action of the light enter into the making of the picture. The examples that I commend to your notice this evening have been produced in the manner I have desired; the two halves of each picture have been joined together, and show in a marked manner the additional action conferred by the atmosphere not being perfectly excluded."

In *The British Journal Photographic Almanac* for the current year, I detailed the results of some experiments I had made, which prove that moisture plays a very important part in this so-called continuing action. The results of these and some others I propose to lay before you. I may as well here mention that all the experiments were made on tissue that had been sensitized in the manufacture. By this means equal sensitiveness throughout the piece is better secured than when the sensitizing is done afterwards. The negatives employed were six reproduced ones of the same subject, and of the same intensity. They are the negatives from which the frontispiece of the last edition of the *Autotype Manual* was printed. You will see by this sheet of prints that they are as equal in density as it is possible to obtain them, and are all well suited for experimental purposes.

On this set of negatives a sheet of tissue was placed, and then exposed to light, but for only half the time that would be required if the prints had been developed at once. It was then divided into six pieces, each a complete picture. One of these was developed for comparison, and you see that it is much under-printed. Two others were put into an air-tight case, the other three were also put into a similar case, but before this was done they were made thoroughly dry in a drying closet.

Twenty-four hours after exposure one of the prints that had not been dried was developed, and you see that it has gained very considerably in the exposure, being nearly, or quite, dark enough. Four days after exposure the second print from this case was developed, and it proved to be nearly insoluble; but by the use of hot water and long soaking a very much over-exposed print was obtained. After seven days one of the prints that had been dried was developed, and you see that no action has taken place, and that the print is no darker than that developed immediately after exposure. Twenty days after the second print from this case was developed with the same results. Sixty days after the last print was tried, and it proved to be nearly insoluble—rather more so than that developed on the fourth day, but by dint of long soaking in hot water a very much over-printed picture was coaxed out. This insolubility and darkening I attributed to the tissue having absorbed moisture when the case was opened to remove the previous prints, as it was much limper than when first put in. The next experiment confirms my opinion.

A sheet of tissue was then exposed on the six negatives as before, namely, for half the necessary time. One was

developed, and the other five put into the drying closet and allowed to remain until thoroughly dry, and then placed into the air-tight case. Fifty days after one of these prints was developed (care being taken in opening the case that the remaining prints did not absorb moisture), and it proved to have gained nothing by keeping. After the lapse of one hundred days another was developed with the same result; and at the end of one hundred and eighty days (six months), another was developed, and you will see that no action has taken place, nor has the tissue become any more insoluble than when freshly made, although kept for so long a time. The remaining two prints I still have in reserve.

These experiments prove conclusively to my mind that the continuing action of light is due to the presence of moisture in the tissue; and that, if it be removed, this action is totally arrested, and prints may be kept for many months between exposure and development without becoming any darker than when first printed.

My next experiments were to determine the effect of the addition of moisture to the tissue for the purpose of accelerating the continuing action, and I must say the results have somewhat surprised me. A sheet of tissue was exposed for half the time, as in the previous experiments, then divided as before, one print being developed at once, and the other five suspended in a chamber the atmosphere of which was kept moist, and at a temperature of 85° F. At the end of an hour a print was developed, and it proved to be over-printed. The others were developed at intervals of half-an-hour, and they all show a continued and regular darkening. That kept three hours it was impossible to develop, as the action had gone quite through the tissue, and the paper could not be stripped off. In the next experiment the exposure was reduced to one-sixth, and the prints kept under the same conditions as in the previous experiment. At the lapse of one hour a print proved, on development, to be nearly dark enough; at one hour and a-half, somewhat too dark; and the others, of course, *much* too dark. The last print of this series was kept four hours, and you will notice that, though so dark, there are some few points that are quite white, showing that the exposure was too short to allow the light to penetrate the densest part of the negative to start the action. It will thus be seen that there is a minimum time which is necessary to set up this action in the extreme high lights.

The next experiment was similar to the last, except that the exposure was one-fourth the requisite time, and the prints developed at intervals of half-an-hour. You will see that the one kept an hour is of the right depth. From this it will be seen that prints that have only received a quarter of the proper exposure will, if kept for an hour in a dark and moist atmosphere at a temperature of 85°, prove quite as good as if they had received the full exposure to light. The other prints are all too dark; in the last one the action had gone quite through the tissue.

The next experiment varied somewhat from the preceding ones, as the prints were kept moist in a different manner, and at a lower temperature. After the sheet of prints was divided, and the first developed, the others were mounted on transfer paper; but, instead of plain water, a seven per cent. solution of bichromate of potash was used, and the mounted prints kept at a temperature of 55° F., one being developed at the end of each hour. You will see that a regular darkening has taken place, but much more slowly than before, four hours being required to bring about the same result as was produced in one in the previous experiments. In a similar experiment, when the mounted prints were kept at a temperature of 65° F., two hours sufficed to produce a fully-printed picture. The reason for using bichromate of potash solution is that the presence of the chromium salt is necessary to produce the effect, and if water had been used instead, the major part of it would have been removed.

NOTES OF COMPARATIVE EXPERIMENTS WITH GELATINE EMULSIONS.

BY H. J. PALMER, M.A.*

THE subject of gelatine emulsions is so well worn by this time that an apology seems to be due for its re-introduction by me to-night. There are, however, still some matters connected with this process which yet require elucidation, and among them that which I propose to discuss this evening. I mean the comparative characteristics of emulsions prepared by the various formulæ which have been from time to time advocated by the chief writers and workers of gelatino-bromide.

Early in the present year I set myself to work to conduct a series of experiments upon a number of emulsions, which might be considered to be fairly representative of the numerous candidates for photographic favour in this process, and I chose for my purpose the formulæ suggested by Messrs. King, Bennett, Wratten, and myself. I have tabulated these below, as follows:—

1. King.	Gelatine 16 grains
	Bromide potass 16 "
	Silver 22 "
2. Bennett.	Gelatine 20 grains
	Bromide ammonia... 7 "
	Silver 11 "
3. Wratten.	Gelatine 18 grains
	Bromide ammonia... 9 "
	Silver 15 "
4. Palmer.	Gelatine 20 grains
	Bromide ammonia... 10 "
	Silver 20 "

These proportions represent the necessary constituents of one ounce of emulsion, and in the preparation the utmost care was employed to secure an exact and accurate composition in each case. I procured, further, some of Kennett's pellicle, and mixed with it an emulsion with water, and also one with beer, in proportion of one drachm to the ounce. My first batch of emulsions were allowed to digest after mixture for twelve hours. I placed them together upon a sheet of iron over a gas jet, at about eight p.m. The gas was turned low, and regulated to maintain a temperature, as I thought, of 90°. I unfortunately omitted to make allowance for the fact that at about 10.30 p.m. in my house a large number of burners would be turned off, and in consequence that the flame in my dark room would be considerably increased in its size. In the morning I found all the emulsions much too hot, and three of them with red fog hopelessly evident. The "King" emulsion, however, remained unimpaired and creamy in its colour, and plates prepared with it were in all respects satisfactory.

The four emulsions were once more concocted with the utmost care; digestion for twelve hours was effected on the bottom shelf of the drying cupboard, the gas under the iron cone having been lighted, and the temperature thus sustained at a moderate point. These emulsions were all satisfactory; and, after the requisite washing, plates were coated with each and left in the cupboard to dry. Very damp and muggy weather supervened, and more than five days elapsed before desiccation was complete, and now another of our tormentors manifested its presence in the shape of blistering films, induced, doubtless, by decomposition. The evil pervaded the "King" plates least, and the "Palmer" plates most of all, and in the "King" plates alone were the usual remedies sufficient to put a stop to the nuisance. The third batch of emulsions was allowed twenty-four hours' grace for the emulsifying process. Washing was effected as usual; twelve plates were prepared from each emulsion, and twelve also from an emulsion composed of equal parts of the four. I coated also some plates with each of the two kinds of Kennett pellicle emulsion, and, as the weather was dry and fine, the whole batch was ready for use in twenty-four hours. In appearance of the films the "King" plates were the creamiest and densest: those prepared with emulsion No. 4

* Read before the Liverpool Amateur Photographic Association.

were the thinnest of all, while Nos. 2 and 3 were about equal in density.

So far, then, I consider that the "King" emulsion took precedence of the other three—(1) in being less susceptible of red fog; (2) in suffering less from the effects of decomposition; (3) in presenting a denser film, and, in consequence, being presumably less liable to halation.

I now placed plates prepared from each description of emulsion in the dark slides, and added others of Kennett's pellicle (both water and beer), Swan's rapid, and both the ordinary and rapid plates made by Messrs. Wratten and Wainwright. All were next exposed upon the same subject, under precisely similar conditions of light, lens, and diaphragm. Each negative received upon one of four sections exposures of five, ten, fifteen, and twenty seconds respectively in a bright light, without sun, and with stop 3 of Dallmeyer's quarter-plate rapid rectilinear. On development the "Palmer" and mixture films were the only plates to show signs of blistering, but the evil was readily cured by the use of the usual remedy. I now tested their receptiveness of density under acid pyro and silver by intensifying one-half of each film. The results are as follows:—

	Requisite Exposure Seconds.	Density	Intensification	Latitude
1. King	15	Third class	Second class	Second
2. Bennett	5	Third "	Second "	Second
3. Wratten	10	Third "	Second "	Second
4. Palmer	30	Second "	First "	Second
5. Mixture	15	Third "	Second "	Second
6. Kennett's pellicle ...	10	Third "	Second "	Second
7. Ditto with beer	20	First "	First "	First
8. Swan	5	Fourth "	Third "	Third
9. London rapid	2½	Fourth "	Third "	Third
10. Ditto ordinary ...	10	Third "	Second "	Second

In rapidity, then, I found the London rapid first; the Swan and Bennett second; Wratten, Kennett's pellicle, and London ordinary, third; King, and mixture, fourth; Kennett-beer, fifth; and Palmer, last. In density and general brilliancy the Kennett-beer were far the best, and the rapid plates the worst. The earliest to take intensification were the Kennett-beer; the most averse to it the Swan and London rapid. The Kennett pellicle plates gave the greatest latitude of exposure, and the rapid plates the least.

The above classification may, I think, fairly represent results likely to be attained with each of these various kinds of gelatine plates in the hands of an amateur of average skill and experience. It confirms the opinion I have always held, that for ordinary landscape work the most reliable emulsions are those which are slow in character; that the addition of beer gives density, brilliancy, and latitude, and without unduly prolonging the necessary exposure; and that for portraiture and subjects on the move, the rapid plates of Messrs. Swan and Wratten are invaluable.

With regard to the difficulty of intensification of the rapid plates above mentioned, it is only fair to add that they were developed with ferrous oxalate, while the rest were treated with the usual alkaline pyro. In my own experience the only method of redevelopment after ferrous oxalate is by the use of chloride of copper to bleach the film, and then by applying acid pyro repeatedly before adding the necessary quantity of silver, care being taken to wash very thoroughly at each step in the process.

A weak solution of iodine and iodide of potassium has been recommended for use, preliminary to intensification, as the best means of facilitating the process where plates are not readily susceptible of it. The accompanying negative was treated with a wash of iodine over one-half of its surface, and then the whole was intensified with acid silver. Density has gathered to a greater extent upon the portion untouched by the iodine, and the latter has caused an unpleasant stain in the film.

I trust that these notes may be of use to those who are proposing to try gelatino-bromide during the coming season. That "comparisons are odious" in things personal I readily

admit; but there are matters in which they are not invidious, but useful and salutary. I trust that you will agree with me in thinking that this is so in the case of gelatino-bromide emulsions.

PHOTO-MECHANICAL PRINTING.

GELATINE RELIEFS.*

THE value of any given product must needs depend primarily upon two conditions, namely, first, its adaptability to its special purpose; and second, upon its cost—that is, the expenditure of time and labour in producing its ultimate results. Applying this principle to the estimation of photo-mechanical processes, an analysis of their relative value will be easy. Such an analysis will be found to divide the subject into two heads, the first relating to the æsthetic nature of the result, and the second to its practical utility. The higher problem which offers itself for solution in this, even more than in other departments of industry, is the combining of the two qualities in the greatest possible degree. Thus the method of producing the silver photograph possesses a higher æsthetic value, while the means employed in producing a printing-press impression have a greater practical one. The problem is to unite the two qualities.

In considering the results attained in utilizing the various graphic processes which come within the province of our subject-matter, it must not be forgotten that the one purpose above alluded to, the combining of the æsthetic with the practical—in other words, of quality with cheapness—was the main object in view. And, in so much as quality, after all, is the greater element of value, so the efforts of investigators were primarily directed toward the improvement of results in this direction. The object has been the attainment, first, of the qualitative result, and secondarily, the quantitative. When the means for producing the Daguerreotype picture had been developed to the greatest possible degree first in the quality of the result, and then in the rapidity and cheapness of its production, attention was directed into other channels, and the method was presently supplanted by others employing the photo-sensitive silver salts, and these again, having reached a high degree of perfection, are supplemented by the use of chromic compounds, in one direction toward the attainment of greater durability and perfection, and in another direction toward more extended utility and cheapness.

In the matter of pictorial illustration, means were demanded for more rapid and cheaper methods than were formerly in vogue, and though in the matter of quality the popular taste and capacity of appreciation requires to be educated, it itself has supplied the stimulus in the matter of quantity. And though the constantly increasing excellence of the results has, perhaps, not been greater than popular taste has demanded, it may be said to have fully kept pace with that demand. The most rapid and cheapest means of multiplying pictorial illustrations is that of the ordinary printing-press. For this purpose it is necessary that the plate from which the impressions are to be multiplied should hold the design in the form of a matrix—that is to say, in relief—all other methods proving slower and more expensive. The one great problem offered for solution to the workers in this field has thus been to provide means by which the highest possible quality of the result could be combined with the greatest facility in its production. The result, so far as it is developed up to the present time, is what is known as the photo-relief plate, obtained in some one of various ways on a chrome-gelatine film.

The various etching methods did not afford an adequate solution of the problem which had been raised, and the latest phase of the subject is marked by renewed attention to the qualities and possibilities of the chrome-gelatine compound. Among the earliest followers of Precht were Tessie du Motay and Courtenay, both of whom made use of the swelled gelatine film. The latter obtained a patent for a process consisting of making the exposure as usual on a chrome-gelatine film, soaking the latter in water until all

the bichromate had been washed out. The plate is then flowed with a solution of iron or pyrogallie acid, in which state it was used as a matrix upon which to obtain an electrotype deposit. An improvement upon this method was patented by Levy and Baehrach in 1875, and is known as the Levytype. This process consists essentially of soaking the exposed chrome-gelatine plate, after wetting or partially swelling it in water, in a solution of nitrate of silver, which combines with the bichromate of potash in the film to form a bichromate of silver. The formation of this latter compound leaves the sunken line of the matrix sharp and defined, at the same time that the swelling of the film raises the groundwork to a sufficient degree. From this, electrotype casts may be obtained directly on the film, or plastic casts made from it, from which in turn stereotype plates can be obtained. In the former case, the swollen film, now consisting of bichromate of silver, is reduced into the form of a deposit of metallic silver by means of a bath of acidified solution of sulphate of iron. This reaction is allowed to proceed until all the bichromate of silver on the film is reduced to the metallic state. It is then treated with a solution of sulphuret of potash, which changes the deposit into the sulphuret of silver, and this covering is sufficiently electrolytic to receive the battery deposit. If a stereotype plate is required, the film of bichromate of silver is treated with a solution of the subsulphate of iron, and the plaster cast then taken in the usual way. The first plaster cast being, of course, in relief, a second cast is then made from the first. This second cast has the lines sunken, like the original gelatine plate, and forms the matrix into which the type-metal is cast, thus yielding a stereotype plate in which the lines are raised and the ground sunken. In all cases of the gelatine relief, the ground is sunk to but a slight and, in all the wider spaces, an insufficient depth below the surface. To deepen these spaces sufficiently to prevent them from inking in the press, mechanical means, such as "routing" machinery, are employed.

The reader will not fail to have taken cognizance of the essential difference between the various "lichtdruck" or half-tone processes and those whose results are to be utilized in the ordinary printing-press. In the former the various degrees of light and shade are brought about by a homogeneous mass of tone or colour, almost or entirely transparent in the high lights of the picture, and increasing in depth of tone until it reaches the full opacity of the deepest shadows. In a printing-press impression, however, there is no difference in the tone or colour in one part of the impression as against another part. The same ink, and to a like amount, is present over the whole print. The effects of light, shade, and shadow are produced by lines of various degrees of fineness or proximity. To obtain a plate consisting of lines forming a design, on a gelatine film, the latter must first be impressed by light through screen or negative containing the design. Such a negative cannot be produced by direct photography from the object itself, as a natural negative has the lights and shades in half-tone. It must be produced from a picture or design which is itself composed of lines so disposed as to produce the effect desired.

It thus becomes apparent that the production of a photo-relief plate requires a drawing or other design in lines or stipples, from which the transparent glass negative can then be made. Through this negative the light is allowed to act upon the gelatine plate, and the work then carried through its subsequent stages. The necessity of the original being in the form of lines being thus stated, it becomes at once manifest that the quality of the result depends primarily upon the draughtsman. The nature of the work required of the artist in this case is, in many senses, peculiar, and hitherto the supply of draughtsmen capable of executing such drawings acceptably has not been equal to the demand. The deficiency, however, is being rapidly supplied, and the constantly-increasing range of utility to which the photo-mechanical arts are attaining opens wide a new and promising field for industrial and artistic labour.

PHOTO-COLLOGRAPHIC PRINTING—THE "ARTOTYPE PROCESS."

WE have before us a marvellously fine example of photo-collographic printing, the work of the Autotype Company. It is the presentation print of the Photographic Society of Great Britain, printed from a negative by the Military School of Engineering, stationed at Chatham, the scene being in the river at Bettws-y-Coed, N. Wales. As a rule, portraiture is considered the most crucial test of the excellence of a process; but it has often appeared to us that landscape—especially some landscapes—more readily revealed the shortcomings of a photo-mechanical printing process than even portraiture. A view like that before us, consisting of masses of foliage and rocky boulders, would very surely show any defects in the printing process. The results here are scarcely at first distinguishable from silver printing, such difference as may be detected on careful examination really being, we think, in favour of the mechanical print. As a presentation print, this is worthy of the Society, and the selection is based on a right principle, as presumably illustrating the present standard of photography. The negative is that of one of the prize pictures at the last exhibition, and the printing is by one of the most recent and perfect photo-mechanical processes.

It is somewhat a curious circumstance that photo-mechanical printing generally has made less progress in England than in other parts of the world. The Woodbury process, it is true, is not only better done in England than elsewhere; here its results seem to be absolutely perfect, whilst in America it has proved a failure. Photo-collographic processes, especially, have not taken kindly root in this country, or proved, generally, commercially successful. In continental Europe they have, on the other hand, made great progress, and have, so far as we learn, been commercially successful. In America, very curiously, they seem to have remained for a long period dormant; but have recently made a leap into excellence and popularity. The introduction of a method of photo-collographic printing, named *Artotype*, and the establishment of a company for teaching the process and selling the licences, have given a sudden impetus to, and interest in, this mode of mechanical printing. But these things would have effected comparatively nothing if the subject of the propaganda had not been transcendently fine. If the process itself—or, rather, its results—had not been marvellously superior to the general run of photo-collotypic prints, the most skilful and earnest propagandism would have availed little. The process is introduced to Americans by one of the most skilful and successful of agents, or, to use an unfairly disparaging term in vogue in the States—"process mongers"—Mr. T. Sarony Lambert. Such an agent will take care that the public know

all the merits of the process he has to introduce; and for a perfect success amongst American photographers these merits must really exist and be very tangible. We learn from the American journals that it has been taken up by a large number of the profession, who, having worked it, speak in high terms of it. Indeed, the most curious part of the business is, that many are apparently adopting it for the ordinary production of portraits. If this can be done, a degree of facility in working it is implied which does not usually pertain to photo-mechanical processes. We have seen examples of the process, sent from various sources, and we have recently received a parcel of miscellaneous examples from the Company. We prefer to avoid comparisons as far as possible; but we cannot accurately describe these without saying that they are beyond a question the finest photo-mechanical prints we have seen, and that they surpass the majority of silver prints, both in delicacy, richness, and force. When, added to this, it is remembered that they are printed in printers' ink, and have consequently the same permanency as an engraving, it will not be surprising that the enterprising photographers of the United States have so largely adopted the process, even in the teeth of a degree of opposition which to lookers-on must be as surprising as it is amusing.

The "Artotype" process owes its invention to Europe. It is, we understand, the most recent and improved form of collographic printing patented by Herr Obernetter, of Munich. So far as we know, it has not been patented or introduced in any form into this country. Especial importance is attached by the advocates of the process to the improvements which Herr Obernetter has effected. We have repeatedly given the various formulæ hitherto in use in preparing photo-collographic prints. We now subjoin, for the benefit of our readers who are familiar with photo-collographic printing, or who may wish to try it, the modified formula of Herr Obernetter, to which, presumably, much of the rare excellence we have described is due. Here are the details:—

"Coat any transparent or non-transparent surface with—

1st Solution.			
Water-glass	3 parts
Water	8 "
Albumen	7 "

"Allow the plates to dry in a rack; then place in the oven and coat with the—

Sensitizer.			
Gelatine	50 grams
Fish glue	50 "
Water	1000 "
Bichromate of ammonia	15 "
Chloride of calcium	none
Alcohol	none

The mode of printing has been often described in our pages, and need not be repeated now. To secure success, great care and some skill are undoubtedly necessary, as the printing process demands similar skill to that of a lithographic printer. Should such a process ever come into general use amongst portraitists we think it is probable that the printing would be best effected by professional printers who have acquired skill by experience, who might with advantage devote themselves to working for the profession.

FRENCH CORRESPONDENCE.

MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE—
COURSE OF LECTURES ON PHOTOGRAPHY—TRAVELLING
PHOTOGRAPHIC APPARATUS—NEW PROCESS OF PHOTO-
COLLOTYPE—ACTION OF COLOURED LIGHT ON STAINED
BROMIDE FILMS—COLLODIO AND GELATINO-BROMIDE
EMULSIONS.

Meeting of the Photographic Society of France.—At the last meeting of the Society, held on the 2nd of May last,

a great deal of business was got through. I shall endeavour to give as full an account of this meeting as I possibly can within the limits of the space allowed for my letter.

Course of Lectures on Photography.—In opening the meeting, the President of the Society, M. Peligot, announced that, by an arrangement entered into between M. Milne-Edwards, Dean of the Faculty of Science at Paris, and M. Davanne, the latter had agreed to give in one of the halls of the Sorbonne a course of a dozen lectures on photography; these lectures would be given probably on Thursday evenings, commencing in the month of November next. The movement of the popularisation of the science of photography, of which I felicitate myself on being one of the principal promoters in France, is thus being extended. A course of the same kind has been already established at Brussels under the charge of M. Léon Rommelaere; a programme of it has been forwarded to M. Davanne by M. Peligot.

Travelling Photographic Apparatus.—M. Klouzard exhibited to the meeting a portable camera and stand of his own construction, in which he has effected considerable improvements. I shall not attempt to give a description of this instrument, but content myself by saying that it exhibits a combination of convenience, simplicity, and lightness, and possesses all the advantages that can be desired by tourists. The camera shown at the meeting is constructed to take plates of about 15 by 21 centimetres.

New Process of Phototypie.—A new process for taking photo-collotypes was described by M. Leon Vidal. This process is quite different from the one now in use, and, according to the author, will render this kind of photographic printing much easier and better adapted for manufacturing purposes. The printing surface is obtained separately, precisely as an ordinary carbon print on a glass plate finely polished, and previously coated with some fatty substance to facilitate the subsequent removal of the image. When the image is completely developed, so as to show the faintest half-tones, a mould in the shape of a frame bevelled on the inside, and of exactly the same size as the phototype plate is intended to be, is placed on the glass plate, and a solution of which the composition is as follows is poured into it:—

Water	100	cub. cents.
Gelatine (ordinary tough)	20	grammes
Glycerine	40	"
Gum-arabic	20	"
Ammonia alum	0.5	"
Salicylic acid	2	"

Alum is added to make the composition hard and capable of resisting mechanical pressure, and the salicylic acid acts as a preservative. This mixture is poured on the carbon print, and fills the interior of the frame by which it is moulded, so as to have a reversed bevel. The layer of composition then forms a plate with a hygroscopic surface, or, in fact, an artificial lithographic stone bearing a transfer of the carbon print, which then forms the image, from which an impression can be taken. When completely freed from any excess of water, the cake of composition must be from five to six millimetres thick, and this serves as a guide to the thickness which the mould must have to contain it. This plate is then placed in the chloride of calcium box, when, at the end of one or two days, according to the season, it will become dried to the required extent. Lastly, the whole layer is stripped off the glass plate and mounted on a copper plate, which must itself be raised on a wooden support, so as to bring it up to the height of the type with which it is to be used. Thus we have a collotype plate which can be inserted in the text of a work, and which will give a large number of prints without requiring fresh wetting, provided only sufficient moisture has been added to saturate it before going to press. By this arrangement we are able to treat separately, on the one hand the printing image, and on the other

the hygroscopic surface on artificial lithographic stone, and this permits us to give to each of these essential parts the special properties which it ought to possess. The one must be before all things ready to absorb fatty substances, and the other to repel them completely. According to the author of the communication, the method that he describes is the only one by which photographic prints in fatty ink can be pulled simultaneously with type. It must be borne in mind, too, that these pictures have the graduated and modelled half-tones of negatives taken from nature; by every other process we can obtain only metallic plates in which these gradations are produced by hatching or stippling, thus rendering rather an interpretation than a faithful copy of natural objects. M. Vidal confined himself to giving merely a descriptive outline of his new process, and proposes on some future occasion, and in another place, to enter more at length into the details, and to point out the various applications which the process admits of. When it is well known it will, in his opinion, have the effect of stimulating considerably the extension of collotype printing. Prints of this kind have hitherto had a very limited production, because, although delicate and refined, they are not very constant in quality, unless executed by a very skilful operator: by the new process, on the other hand, collotype plates can be produced and worked on a large scale, and every printing or lithographic establishment will soon obtain workmen sufficiently trained to carry it out. M. Vidal more particularly drew the attention of his audience to the special character of the printing image; it exists, in fact, on the layer of gelatine in relief, which relief can be varied according to need; while in the collotype plates hitherto used, the image is depressed or engraved. This is a great advantage, which will be appreciated by all who work this kind of printing.

The Action of Coloured Light on Stained Bromide Films.—As regards the other proceedings of the meeting, they were devoted almost entirely to the burning question of the day—collodio and gelatino-bromide emulsions. But before giving an account of the various communications on this subject, I had better give a short abstract of a paper read at the meeting by M. Cros, on the means of modifying the chemical action of light on sensitized plates according to the way in which they are prepared in relation to the effect desired to be obtained. This paper was a resumé of one which, under the title of "On the Action of Differently Coloured Light on a Film of Silver Bromide impregnated with Various Organic Colouring Bodies," he had already submitted to the Academy of Sciences. His object is to be able to reproduce natural objects in similar tints to those obtained by the artist *en grisaille*; that is to say, with the true effects of light and shade as seen in nature, and avoiding those of the red and yellow, which to the eye are luminous, but in photographs are rendered by black shadows. It is, in fact, the whole question to which I have so often directed the attention of experimenters—that of obtaining a negative in which the different colours preserve their proportional value. M. Cros shows in his communication that a collodion containing three per cent. of cadmium bromide, and sensitised in a twenty per cent. bath of silver nitrate, will give a sensitive film capable of realizing the required conditions. The film must be carefully washed, and, to remove all trace of silver nitrate, it must be rinsed in a three per cent. solution of potassium bromide, and then again well washed to get rid completely of any remains of the latter salt. When thus treated, the film is quite free from soluble salts; it may contain some very delicate organic bodies, but, in the absence of light, these will not be the cause of disturbing action. On a film prepared in this way Mr. Cros forms an alcoholic solution of turmeric, either alone or mixed with a tincture of carmine; he then washes it to remove the alcohol until all greasy marks disappear. When exposing, which is done in the ordinary way, he

interposes between the object and the lens a flat cell containing a solution of potassium bichromate, thus permitting only orange-coloured light to enter the camera. In this way M. Croes has succeeded in photographing the red and even the ultra red of the spectrum, and as the action of the violet and blue rays is suppressed, he produces a grey-tinted negative with the same effect of colour as seen by the eye. In a similar way, with a tincture of chlorophyll, the chemical action can be reversed, and the red of the spectrum obtained to the exclusion of the violet; when, therefore, we have succeeded in completely reversing the spectrum, we can, by a proper use of the modifying substances, direct the chemical action so as to produce the desired effect. These theoretical views no doubt are as yet wanting in practical conclusions, but they open a path for investigation at the goal of which will certainly be found the solution of the important problem how to obtain a negative with the effects of the different colours in their proper relative proportions.

Collodio and Gelatino-bromide Emulsions.—I now come to the subject which occupied the greater part of the time of the meeting—emulsions both of collodio and of gelatino-bromide. The subject was opened by a letter of M. Fabre, of Toulouse, in which he called the attention of the Society to one of the results of his researches—the fact, namely, that the collodio-bromide emulsion of M. Chardon is not so efficient when old as when it is recently prepared; it is necessary, he found, to let it dry before washing it. M. de Lafolaye also, through the medium of M. Davanne, described an experiment he had made in preparing emulsions by a different method to that given by M. Chardon; he had found it preferable to precipitate the silver bromide from water, to wash it with alcohol, and then to incorporate it with the collodion. A negative taken with emulsion prepared in this way by M. Lafolaye shows very great delicacy. M. Andra had tried the same method, and had obtained similar results. M. Dardy wished to know whether the same method could be adopted for the preparation of gelatino-bromide, and showed some of his own attempts in this direction, which, however, scarcely appeared to be conclusive. M. Stebbing believed that it would not answer for gelatine. M. Aimé Girard remarked that some means of effecting the object in question would no doubt be discovered; he thought that probably it might be found by obtaining perfectly neutral silver bromide in a highly subdivided state, and he recalled his often proved chemical experience of the impossibility of passing any bromide or chloride through the filter so long as the least trace of acidity had not been removed by washing; so soon as that disappeared the bromide escaped through the filter. The required condition must probably be sought for in this direction, as perhaps M. de Lafolaye himself had already discovered. M. Stebbing, and after him M. Dardy, exhibited enlargements of gelatino-bromide negatives formed on the exterior surface of the gelatine film which had been separated from the plate. M. Stebbing had obtained a very fine and regular negative, with all the lines correct, enlarged about four times, and transferred to a plate four times as large as the first. M. Dardy has been equally successful. The latter advantage is for the moment a defect which must be, if possible, avoided; it is manifested in some kinds of gelatines, and more particularly in the one with the comet brand. According to M. Dardy the frilling is due to too concentrated a developing or fixing solution; he had been able to correct it directly he observed the defect by reducing the proportion of ammonia and that of hyposulphite, or, in other words, rendering the developing solution less alkaline, and those of either iron oxalate or sodium hyposulphite less concentrated. M. Stebbing showed a series of plates whose delicacy had in no way interfered either with their vigour or their harmony; he stated that he had not experienced the least difficulty in attaining any degree of intensity. As regards their sensitiveness, it was so great that the greater part of the views which he

exhibited contained, as he pointed out, living objects taken while in motion. A non-actinic light is in M. Stebbing's opinion very difficult to attain; he showed some experiments he had made on this subject, all conclusive in favour of chrysoidin, three layers thicknesses of which must be superposed on one another to remove all effective actinism. M. Franek de Villecholle recommended the employment of every possible precaution against the action of the chemical rays—more even in the case of the preparation than in that of the development of gelatino-bromide; he himself uses a pane of glass coated inside and out with collodion stained with chrysoidin. M. Gobert advised operators to keep the film of gelatino-bromide excessively thin; too thick a film is, as he observed, often the principal cause of imperfections. A remarkable collection of negatives in gelatino-bromide was exhibited by M. Moizet; they had only had an exposure of from two to three seconds. M. Balagny showed some beautiful negatives taken on collodion emulsions, and pointed out that he had secured the very complete uniformity which characterised them by employing the method of Mr. Bolton; this consists in pouring the emulsion into a dish, letting it dry, cutting it into strips, and then washing it in boiling water. He guarantees, if this method be used, an absolute constancy of result. Unfortunately, this emulsion requires an exposure of fifteen minutes, where one of gelatino-bromide only takes a few seconds, and excellent as are the negatives which M. Balagny obtains by his method, the words "fifteen minutes" are apt to make us lose temper; it is the speed of the waggon against that of the locomotive. However that may be, we are compelled sometimes to make use of the waggon in spite of the railways, and it is the same with these collodion emulsions—we must not despise them altogether. M. Ferrier submitted to the meeting some excellent specimens of gelatino-bromide pellicle of his own make, and some negatives taken with it. Pellicle is now an indispensable requisite of all travelling photographers. Lastly, M. Chardon read an important paper on the various gelatino-bromides; but it was too long for me to attempt to give even an abstract of it—my letter for this week's NEWS would never be finished within anything short of outrageous limits, and with all my wish to be as concise as possible, I have already exceeded the space that is generally allotted to me. Nevertheless, the Editor and my readers will, I hope, permit me to say a few words about M. Chardon's paper, which constituted in reality a most complete and interesting study of the whole subject of gelatino-bromide. He has tried a very large number of the gelatines generally known, and he has succeeded in giving us a series of formulæ which I shall describe afterwards, but of which the principal is as follows:—

A.—Water	50 cub. cents.
Ammonium bromide	5 grammes
Nelson's gelatine	4 "
Fish glue	4 "
B.—Water	50 cub. cents.
Silver nitrate	9 grammes

B is poured into A, and the whole is kept for three hours over the water bath with frequent stirring. The result is a creamy emulsion, which is filtered into a dish, and, when set, it is cut up and well washed, so as to free it from all soluble salts; the plates must be dried very rapidly. I shall recur to this paper (which has been very conscientiously worked out) on a future occasion; it is important that at least a *resume* of its principal details should be made public. I cannot conclude without referring very briefly to the remarkable collection of photographic prints on lithographic stone, taken with fatty ink, by M. Lamué.

When I commenced an account of this meeting, I alluded to the well-filled agenda paper; in giving only a condensed summary of the transactions, I have made the present letter much too long.

LEON VIDAL.

LIGHTING THE SITTER.

BY O. W. OSBORN.*

IN what follows, I shall attempt to confine myself to a few remarks upon the proper lighting of the sitter, hoping by so doing to perhaps throw a faint ray on the subject, which may (or at least I hope so) do some one a small amount of good. What is the cause of our pleasure when viewing a really fine work of art? To this there is but one answer, namely, the lighting and posing: but as it is the former of which I am speaking, I shall leave the subject of posing for the present. Pick up any well executed photograph, which has been made by an *artist*, and you will observe a wonderful blending of light and shade, without any of those harsh, snowy lights and inky blacks so characteristic of many pictures made in the rural districts. A great many workmen in the country are in the habit of treating all their sitters alike in respect to the lighting, forgetting, as it were, that no two faces require exactly the same treatment. While a light may be well suited to your purpose in photographing persons with round, plump features, yet that light would give you a horrible negative of a person with very prominent features. For a person with round, plump face, the light (that is, the principal light) should strike them at an angle of about 45° from the perpendicular, and proceed from some distance in front and to one side of the subject. A serious fault with many is in the use of a screen on the shaded side of their subject. The screen is all right if it is only used in its right place, which, I may say, is not wholly to one side, but rather inclined to occupy a position more in front of the sitter than many are inclined to place it. Of course the inclination must depend altogether upon the subject you have in charge: if fat and plump, pull the screen away some distance; but if of the opposite sort, move it closer up, all the while watching the various changes and modifications that take place. Care must be exercised, so as not to throw too much light on what should be the shady side of your subject, for if you do, you will meet with a serious trouble in respect to the formation of false lights.

A common fault of many is in placing their sitters too close to the side light, thinking that by so doing they gain increased brilliancy and shortness of exposure: better have no side light, than so sin against all the rules of art by so doing. Brilliancy is not produced by any such means, unless you call hardness brilliancy. In order to secure brilliant lighting, it is essential that your background be of a medium grey tint; not too dark, for that gives a cold, wintry effect, and the light strikes the sitter so that one side is made a little lighter than the ground, while the other is so screened as to be made to appear a little darker; taking care to watch the gradations of light and shade on the face, that they be not too abrupt; to prevent which, use the white muslin screen or reflector mentioned above, and in the manner there indicated. Light proceeding from a number of places, as from too large an opening in the sky or side-light, will have a very bad effect. It not only flattens the picture, but gives the person making the same a very bad reputation as an artist; so see to it that a suitable number of screens are provided, both over head and on the side, to enable you to control your light in a satisfactory manner.

During my fourteen years' experience, I have worked under a great many different lights, some of which were very good, while others were fit subjects for ridicule. Of course, one workman will prefer this, and another that, sort of light; but, for my own part, I find one constructed with a clear northern exposure the very best that can possibly be made. The side light should be about seven or eight feet high by twelve or fourteen feet long, with screens provided with springs or weighted rollers, so that they can be raised from the bottom up, and not the reverse, as

is the method adopted in a great many studios. Skylights should face the north, if possible, and be about twelve feet wide, and as long as the side light, or a little longer would do no harm, and also be provided with light blue or white screens, fastened at their upper ends, and provided with cords and pulleys, so that they can, at the will of the operator, be made to perform all the functions required of such devices.

By having the screen fastened at the highest point of the skylight, and the lowest part of the side-light, you will be better able to control the lights and shadows on the faces of your sitters than if the arrangement was reversed, and the ends made fast, as I have frequently seen, at the point where the side and top-lights join. The operating-room should always be provided with two white muslin screens, for use on each side, but more nearly in front of the sitter. They should form, as it were, a pair of wings to the instrument, thus enabling the operator to vary the effect at will. A very useful contrivance, embodying the same principles, is the Kurts counter reflector, which you can find described at length in Anderson's "Skylight and Dark-room." Of course, an arrangement of the kind just mentioned is only suited to bust pictures or the like; groups always requiring a different treatment.

The other subjects connected with the photographic business, of which the writer would like to speak, will be treated separately under their appropriate heads.

One more thing, connected with the arrangements of the skylight, deserves mention. It is the habit of many photographers to build their lights entirely too flat; or, in other words, not high enough from the floor to the highest point. The skylight should always have what carpenters call a "half pitch," or even a little more than that would not hurt anything, but be more beneficial than otherwise. I need not here attempt to enumerate the many advantages a steep light may have over a flat one; suffice it to say, that your operating room will be drier on wet days than your neighbour's who has a flat light. Where the skylight is steep, as indicated above, and you have to operate in a room fifteen or sixteen feet wide, you will find that much better results will be obtained by placing the sitter seven or eight feet away* from the side-light, thus giving the lower portion of the skylight a chance to assist in illuminating the model, not to add a hundred other advantages to be derived when a steep light is used; but the most important of all will be the relief obtained, which is mainly due to the direction in which the shadows are cast.

The Rembraudt, or shadow picture, although one of the most beautiful styles ever introduced, is, I am sorry to say, slowly losing ground, or, in other words, is not receiving the encouragement from photographers that it should receive. In fact, many refuse to make them altogether; for the reason, probably, that they are difficult to produce. Ignorance seems to prevail among a great many in regard to the method of lighting; nine out of ten use a light entirely too harsh, and that, too, from a window or side-light which is about on a level with the face of the sitter. Such a method is altogether wrong. In my own work I adopt the following method, which can be worked successfully by any one. It is this:—Begin by placing your grey shaded ground near one end of the side-light, and about seven feet away from the glazed surface; swing the side of the ground farthest from the light around away from the light, then put the chair in its proper place, after which you may pose the subject, turning the body still farther from the light. If the subject is round and plump, you can shut off the side light almost entirely, leaving only about two feet of glass at the upper end, after which the skylight curtains must be drawn down to within four or five feet of the side-light, and left there; next move the camera-stand around away from the side-light, after the same

* *Practical Photographer.*

manner as the background, until you come square with the background again; now adjust the rest to the sitter's head, turning the head a little toward the side-light, but not too much so, and step back and observe the style of light at that moment playing over the face of your sitter, and see if it does not resemble what is generally known as the "Rembrandt." A little practice in operating diagonally across your room will show you a variety of effects of light and shade of which the uninitiated would never dream. By causing the light to proceed from a point some distance above and to one side or other of your sitter, you avoid that too common error of many—the melting together of the high lights of the cheek and nose.

Notes and Queries.

A PERPLEXING BATH.

DEAR SIR,—My negative bath is shrouded in mystery, which in vain I have endeavoured to unravel. I write to you in the hope that either yourself or some of your readers may be able to offer some explanation. I mix my bath in the usual manner with distilled water, and 35 grains to the ounce. For a few days the negatives are beautiful and soft, but after that time they are flat and grey, and I cannot get the least roundness or body in them; and after they are washed and allowed to drain a minute or two the surface looks as if they had been thoroughly peppered. I know the bath is not over-iodized, for I iodize by putting a plate in for a few hours. The paper looks the same after sensitizing, so that it must rest either with the water or the silver, of which I have tried various (two) samples with same result. I may add that the bath is "examined" with minute particles even after filtering, and looks like "fluff" from a linen cloth; and the paper bath, after standing an hour or two, gives a black deposit at the bottom of the dish. I have tried every remedy, from sunning to a dose of cyanide, and to no effect. Can you give me any idea as to the cause?—Yours respectfully,

PUZZLED.

[The bath may easily be over-iodized by leaving a plate in for a few hours.—ED.]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on May 1st, at the Society of Arts, John Street, Adelphi, the Rev. F. F. STATHAM, M.A., F.G.S., in the chair.

The minutes of the last meeting were read and confirmed.

THE CHAIRMAN then read a letter that he had received from Mrs. P. Le Neve Foster, in reply to the letter of condolence written by the Chairman at the request of the Society. Another letter was also read that had been received by the President from the Belgian Photographic Society, referring to a competition that is about to take place for the best emulsion process: a present of 500 francs had been presented to them to be awarded as prizes.

Mr. G. F. Williams and Mr. T. O. Dewey were elected as members of the Society.

Mr. A. BRITTLEBANK then handed round to the members, for inspection, proofs of the portraits taken of the President at the last meeting by his new apparatus for burning magnesium.

Mr. W. B. BOLTON submitted for inspection some very fine specimens of portraits taken by ordinary coal gas by Mr. Laws, of Newcastle, in twenty-five seconds. A parcel of pamphlets had been received by the Secretary for distribution among the members, from Mr. J. Buxton Payne, of Manchester—"Developing Instructions for Dry Plates."

The Chairman then called upon Mr. FOXLEE to read his paper on "The Continuing Action of Light in Carbon Printing" (see page 218), which he illustrated by numerous specimens.

THE PRESIDENT said he felt sure that every member present must feel pleased with the admirable paper that had just been read, so well illustrated as it had been, and it only showed how difficulties could be overcome by perseverance.

Mr. BOLAS said that he had often heard it remarked that it was very difficult in carbon printing to get the same results

twice. When the same exposure had been given and no end of pains taken to get the actinometer paper to register the tints as even as possible, and also every precaution to keep the tissue dry, in hopes of getting even results—all had been to no purpose. But what he had just heard from Mr. Foxlee, relative to moisture, could not fail to be a boon to many who had to get off a number of prints in dull winter weather. Success seemed to lay in the requisite degree of dampness to keep up this continuing action, and that was best obtained when the tissue was only slightly moist; but when the tissue was very wet, this peculiar action did not occur so much; and, on the other hand, tissue, when very dry, was very insensitive. It was also a fact that when tissue was sensitized, and just as it was taken off from the bath, it could be carried into strong light; but on drying, the sensitiveness was obtained. He himself had carried wet tissue into very strong light without any injury to it; it printed all right when dry.

Mr. COLLINS suggested that the admirable specimens of Mr. Foxlee's would be very valuable if they could be reduced in size, and issued to the members as a presentation print, as a guide to them for future reference.

Mr. PEARSALL said that he had had no experience in carbon printing, but, gathering from what he had heard, it seemed to him that Mr. Foxlee had cleared up many points.

Mr. AYERS said he did not think that this action applied simply to carbon printing, but, so far as his experience was concerned, also, to a certain extent, to silver printing, for he had found that prints in the frames that had not finished printing over night were found sufficiently done by the morning, and did not require to be out again.

Mr. BOLAS observed that chloride of silver could be exposed to light in a sealed tube without darkening.

Mr. FOXLEE remarked that the examples were kept in a metal case, and others in a closed drawer.

Mr. PEARSALL said that some of this peculiar action might be due to ozone, as ozone was produced under many different conditions, which ought to be taken into consideration.

Mr. FOXLEE, in reply to a question by Mr. Brooks, said that the action was more rapid when the tissue had been mounted with bichromate solution on its supports; but if all the free bichromate were washed out, the action did not go on; so, by keeping the tissue with the bichromate on it in a closet at a certain temperature, a greater number of prints could be got off in bad weather. He further remarked that if he had a novice to teach, he would rather teach him carbon printing than silver, as it was so much less trouble. At the Autotype Works the printers were quite ignorant of silver printing. Not long ago he had to make a silver print, and they were quite astonished to see the image fully out when taken from the frame; they had never seen such a thing before.

Mr. HARRISON then demonstrated the method of forming reflectors for any class of work, to throw the light in any direction it might be required.

Messrs. WRATTEN and WAINWRIGHT passed round for inspection some instantaneous photographs (five in number), cabinet size, of the Oxford and Cambridge boat-race. Mr. Wratten said they were taken under very great difficulty. The train he was in arrived late, and the place he intended to occupy was taken up, so he had to lay a board across the top of some chimney-pots, and do the best he could. The examples were very fine indeed.

Mr. PAYNE JENNINGS said that he had never seen such marvellous examples of instantaneous photography which gave so true a representation of the race on such a day.

Mr. WRATTEN said they were taken with a D lens of twelve inches focal length, and a five-eighth stop, and exposed with a drop shutter; and the negatives were untouched.

Mr. YORK exhibited a very clever and compact apparatus for washing emulsions.

Mr. A. COWAN exhibited a very ingenious instantaneous electric drop-shutter, whereby all vibration of the camera was avoided; which was well received by the members.

Mr. Wm. Brooks said that he had that day received the prospectuses and prize list from the Royal Cornwall Polytechnic, to be held on August 26th, 1879, and he hoped this year to see a goodly number of exhibits; and he also wished to state that it was the only society in the country that offered awards annually for photography, and he only wished members could pay a visit to the Exhibition when it was opened, as he was sure they would be delighted. Another department (a new one) that he wished to call attention to was a

photographic appliance department, for cameras and apparatus, and also the magic lantern, as he considered that instrument was now closely connected with photography in exhibiting its productions. The judges thought it expedient to have this year what they might term an open list, as of late processes and different classes of pictures were so numerous that it would be impossible to enumerate every class; but whatever was sent for exhibition would be fairly dealt with on its merits. Mr. Brooks said that he should also have great pleasure in giving any information respecting any point that might not be clearly understood from the prospectuses, which he would distribute to the members, by writing to him at Reigate.

According to the notice given at the last meeting, a certain amount of the surplus presentation prints were then disposed of. A few are still remaining, which will be disposed of at the next meeting.

Mr. HARRISON said he would describe at the next meeting a new apparatus for artificial light; and Mr. BRITTELBANK would also read a paper, which would be duly announced.

The meeting was then adjourned.

PHOTOGRAPHIC SOCIETY OF VIENNA.

An ordinary meeting of the Society was held on the 11th March under the presidency of Dr. E. HORNIG.

A communication was received from Professor J. HUSNIK, containing remarks on the photographic reproduction of linear and stippled drawings. For this purpose, he observed, the asphalt process gave the sharpest and clearest pictures, but was attended by many difficulties. Among these difficulties more especially are the circumstances (1) that the size of a plate in the asphalt method is limited to a square foot at most; (2), that the zinc plate used as a support must be highly polished, which renders it very expensive; (3), that the asphalt is sensitive in only a slight degree. Photographs of line drawings have been obtained now for some years by means of photo-lithographic transfer paper, but it is not generally known that stippled drawings can be reproduced quite as successfully by the same means. Professor Husnik obtained these photographs himself, by passing his gelatine paper through a glazing press, thus obtaining a highly polished surface capable of reproducing the most delicate and finely gradated shades of the drawing. The difficulty of preserving the photo-lithographic paper for any length of time in a sensitive state he has overcome by keeping it in a box whose floor is covered with ammonium carbonate.

Dr. J. M. EDER sent a report on some samples of collotype gelatine by Heinrichs, of Höchst-on-the-Main. He has examined three kinds of their gelatine distinguished by the letters L, H, C; they are all nearly colourless and transparent, soften quickly in cold water, and melt at about a temperature of 33° C. All three sorts, either before development or during that operation, became perceptibly grained, which is very necessary for collotyping. The quality L seemed to be best adapted for collotypes, as it possessed the greatest power of resistance; the quality H, on the other hand, is most suitable for the carbon and other similar processes, as it is more soluble, and thus materially promotes the development of the image.

The PRESIDENT remarked, that after Dr. Eder's report, the dealers in photographic materials would no doubt keep all these gelatines in stock; and

Herr J. ALBERT, of Munich, who was present at the meeting as guest, stated that for his own business he had been in the habit of ordering his gelatine direct from Messrs. Heinrichs.

Another communication was read from Prof. HUSNIK, on his experiments on the intensifying of negatives, photographs of prints, and engravings. The lead intensifier of Dr. Eder, he had found in many cases not only difficult to use, but uncertain in its results. He had tried various other means for intensifying negatives, and found the only one on which he could rely to be a solution of protochloride of mercury in iodide of potassium. The negative he first prepares entirely by the wet method, using only a pure iodized collodion, and developing with iron and sugar. Upon the strength of the developed picture depends entirely the method of intensifying. If the image be sufficiently vigorous, it is at once washed, and fixed with hyposulphite; but if the exposure had been too short, it must be strengthened with pyrogallic acid previous to fixing. Afterwards the picture is intensified with the solution of mercury chloride and potassium iodide. In many cases the solution of chloride alone would suffice, but if that does not give sufficient vigour, then the solution of mercury in the iodide must be employed. This latter is prepared by precipi-

tating the iodide of mercury from the solution of chloride by potassium iodide, and redissolving the red precipitate in excess of the potassium salt.

Herr JAFFE believed that Prof. Husnik had exaggerated the difficulties of intensifying by means of a solution of lead; he had found this process give good results, although the solution of mercury iodide might be used occasionally with advantage. Plates might be left in the lead solution for a considerable time while the operator could go on with his other work, and any green fog which might arise from defective washing could be removed by hydrochloric acid.

A discussion arose on the extra-rapid process of M. Boissonas. The president stated that he had only heard of Klary's experiments in Frank's studio (though now M. Klary was disavowed by M. Boissonas), but Herr ANGERER, who had been present at some of these experiments in the company of Prof. Kollar, of Pesth, explained that the results were by no means satisfactory.

Herr LUCKHARDT referred to former reports of his in a number of so-called instantaneous processes, of which he maintained that only those of Messrs Chambay and Krole met all the requirements of an extra-rapid process, and one of the members present informed the meeting that Herr Krole's process would shortly, by arrangement with a manufacturing house of photographic materials, be made available to a large circle of customers.

PHOTOGRAPHIC SOCIETY OF BERLIN.

At the usual fortnightly meeting of this Society, held on the 3rd April, Professor FRITSCHE exhibited a large number of Col. Woodward's photographs of microscopic objects, demonstrating the enormous progress which micro-photography has made of late years. It is almost incomprehensible that at a distance of ten metres between the sensitive plate and the objective, which latter is hardly larger than the head of a pin, such perfectly modelled and equally illuminated images could be produced. A unanimous vote of thanks to Prof. Fritsch was passed, and he was requested to express to Col. Woodward the acknowledgments of the Society.

Herr DUBY inquired whether, for correcting the difference of focus, Professor Fritsch had adopted an absorption cell filled with a solution of the ammonio-cupric oxide, or a displacement of the ground glass plate.

In reply to this question, Herr FRITSCHE explained that to the screw micrometer of the objective he had fitted a toothed wheel, into which a pinion of half the pitch was geared. By this means an excessively small motion could be impressed on the screw-micrometer, and the distance through which it was turned could be easily read off. A strip of glass with fine lines engraved on it is placed across the stage, and by means of it the difference of focal length is determined; it is then adjusted by turning the pinion so as to advance or draw back the objective.

Herr KARDATZ described an arrangement that he had seen in a photographic studio in San Francisco. This consisted of a screen of wire netting placed at about the distance of a foot from the roughly painted background, which had the peculiar effect of concentrating all the vigour of the image, and consequently the attention of the observer on the portrait itself, while the background became more indistinct.

Herr SUCK referred to the practice which at one time prevailed of stretching a piece of gauze in front of the background, with the object of giving greater softness to the picture. The plan, however, failed in producing a satisfactory result, though probably a wire netting with a rough background would be more effectual.

Herr DUBY laid before the meeting a number of photo-mechanical prints from the works of the Photo-Engraving Company of New York. Great admiration was excited by the perfection to which this kind of printing had been brought, and it was determined to keep for some time the collection on view for the benefit of the members.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday next, May 13, at the Gallery, 5, Pall Mall East (the summer exhibition of the Society of Painters in Water Colours being on view), when, in addition to other matters, a paper will be read

by Mr. C. Bennett, closing the discussion upon gelatine emulsions.

PRESENTATION PRINT.—The presentation print of the Photographic Society of Great Britain is now in course of issue to members. It is the fine view at Bettws-y-coed which obtained for the School of Military Engineering at Chatham a prize at the last Exhibition, printed by the Autotype Company in printing ink of the photo-colligraphic process, of which it is a very admirable example. There is one curious omission, the result of an oversight on the part of some one. The producers of the negative, the fact that it was a prize print, the place where the view was taken, the name of the printers, are all duly set forth; but there is no allusion to the fact that the picture is the presentation print of the Photographic Society of Great Britain.

CATALOGUE.—We have received a copy of the interesting catalogue of Messrs. Watson and Son, opticians, of High Holborn. It contains details of an extensive assortment of lenses and apparatus generally, as well as other photographic requisites, which it will be greatly to the advantage of photographers to consult, especially all those who may contemplate increasing or altering their stock of photographic appliances.

PORTRAITS BY GAS LIGHT.—We have been favoured by Mr. Laws, of Newcastle-on-Tyne, with a further example of portraiture by ordinary gas-light. An excellent cabinet produced with an exposure of 25 seconds is brilliant and finely modelled. The burner consisted of 68 jets, with an illuminating power equal to 1,250 candles. The exposure for eard portraits is about 15 seconds. We hope to have more to say on this subject shortly.

COLLODION AND GELATINE FOR EMULSION.—Mr. Obernetter says, in speaking about the gelatine plates sensitized with bromide of silver, that they are the most sensitive plates he ever used, but the drawback to them is the drying and the trouble of developing them. He therefore prefers the bromide emulsion, which he plunges, after being set, in a solution of 1 part gelatine, 30 parts of alcohol, and 20 parts of warm water. Plates thus prepared can be kept for some time, while others not coated with gelatine will have to be developed right after exposure.

CARBON IN AMERICA.—Mr. Gentile, an enthusiastic carbon printer, writing to the Editor of the *St. Louis Practical Photographer*, says:—"I want you, friend Fitzgibbon, to urge on all those who have invested their money in carbon not to be such fools as to abandon it, but to go at it again with renewed energy. But they must go to work in the right way; not like a firm in New York are doing, as told to me by our mutual friend Howard, of the State of New York carbon fame. They had a distinguished individual to whom they paid the very liberal salary of three dollars per week (about twelve shillings) working carbon for them, but with very indifferent success. How could they expect otherwise? A really skilful printer ought to be worth nearly as much as an operator. One of the firms that I mention in this letter pay their carbon printer thirty-five dollars per week (about seven pounds), but he is a success. In conclusion, I will only say to all those who are interested in the progress of photography, that Mr. Lilienthal, who takes great interest that others also may succeed in working carbon, is most willing to impart to all those who wish to come to his studio a thorough knowledge of his *modus operandi*. And I, as the President of the Carbon Society, which I hope to see give a good exhibition some day not far distant (St. Louis, I think, would be a good place), assure all carbon licencess that the fault of non-success lies with them, and not with the process."

A NEW MEASURE OF ACTINISM.—It has been maintained by Schoenbein and others that perfectly pure sulphuric and nitric acids containing no trace of nitrous acid would not produce any change in iodide of starch. Professor Leeds stated that he had been unable either to obtain acids so pure, or to make them himself, but that his iodide of starch solutions were invariably affected by them. Upon reasoning on the circumstance, it struck him that iodides might be decomposed by light in the presence of acids, a supposition which afterwards proved true; and he based upon it a method for measuring the relative actinic effects of different kinds of light. Upon exposing such solutions for the same length of time to the sun's rays, to the electric light, and to a magnesium light, and then comparing the results in a colour comparator, he was surprised to find that the electric light had produced over three times as much chemical effect as sunlight, while the action of the magnesium light was but a very small fraction of it.

To Correspondents.

R. G. F.—The effect of distemper colouring is excellent for portrait backgrounds, but the screens are easily injured, and not easily repainted by amateurs. On the whole, we think oil flattening answers best for backgrounds. To produce such a flatted surface, mix the paint with the slightest possible trace of oil, using turpentine almost entirely. Some skill is necessary in applying the paint.

O. P.—In precipitating a negative bath with carbonate of soda, we have often noticed that towards the end, a dirty bluish-black solution has remained, containing the impurities of the solution; this has been and should be rejected. 2. The scum you describe is generally present. We remove it with strips of clean blotting-paper drawn over the surface of the solution before immersing a plate.

JENNY J.—They were collodion positives to which you refer, and the effect was produced by a secret formula, in which a solution of bichloride of mercury was a principal element. Ferrotypes may also be whitened with bichloride of mercury. The question of permanency of such pictures is a difficult one, as some fade or darken rapidly, whilst others remain unchanged. If the bleaching be carried as far as possible, we believe that the result will be tolerably durable. Its tone will, of course, be lowered by varnish.

GODOLPHIN.—Chloroform is the best solvent of india-rubber that we know. Some samples of benzole do not readily dissolve india-rubber. When there is any difficulty, the best plan is to shred the india-rubber as small as possible, then cover it with chloroform, which will readily dissolve it, forming a paste, which may then be easily dissolved or diluted with benzole as required. Bisulphide of carbon is a good solvent, but it has an offensive smell.

R. F. L.—Marine glue answers well as a cement for glass in making glass baths. The pieces of glass must be made hot, and the glue melted. This is best done by bringing it into contact with a flame, or by putting bits in an iron spoon and holding that over the fire.

G. G.—In our experience a strong developer gives a softer and more detailed negative than a weak one. We should call thirty to fifty grains strong, and five to twelve grains weak. A weak developer develops slowly, and gives more intensity to the high lights relatively than a strong one.

J. H. MORTEN.—Judging from the examples enclosed, your lens is of too short a focus to do justice to standing eard portraits. You may improve the definition by using a small stop, but that will prolong the exposure. Most ordinary quarter-plates will do for bust eard portraits, but not for standing figures. Your half-plate will give better covering definition for such figures; but the focus is too long for good results. With the thick atmosphere often prevailing in this country it is desirable to avoid the use of a lens of too long a focus; the mass of misty atmosphere is photographed as well as the figure, and the result is a dull foggy looking picture. A lens made for eard work will answer best.

G. R. L.—It is evident that your negative is too thin; it sadly lacks intensity, and hence the flat grey prints. Lack of intensity may be due to many causes: the use of new collodion, over-exposure, the use of a strong developer, bad light, driving off the free silver in applying the developer, and other causes. Probably using the collodion somewhat riper will help you. The addition of one grain of pyroxylene per ounce of collodion is often useful in such cases.

EXPERIMENTALIST.—To make paper prints or negatives transparent, apply white wax. Sometimes the wax permeates more thoroughly if the negatives have been soaked for a short time in hot water, to remove the size. The wax must be melted, and the paper saturated with it, and afterwards ironed between two sheets of clean blotting-paper, to distribute it equally and remove excess.

ST. ASAPHIS.—Dry plates most undoubtedly answer best for long exposures. It is possible to give an exposure of an hour with a wet collodion plate; but it requires precise conditions to do this with perfect success, and the risk of stains, &c., is very great. With dry plates there is no such trouble, and you may buy them ready prepared if you wish, in which case you have only to expose and develop them. Indeed, in some cases, it is possible, we believe, to reduce the trouble still more, as the manufacturers will, if proper arrangements are made, undertake to develop them as well. But it is wiser to acquire skill enough to develop at least for yourself.

A YOUNG HAND.—There is no absolute standard for the strength of baths. As a rule, a negative bath may vary from 30 grains to 40 grains of nitrate of silver per ounce. The printing bath varies more, from 20 or 30 grains to 100 grains and upwards being occasionally used. About 50 grains, or a trifle less, per ounce are most commonly used.

S. F. CLARKE.—The letter was duly forwarded. Several Correspondents in our next.

The Photographic News, May 16, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

AN EYE TO COLOUR—GELATINE PLATES ABROAD—INFLUENCE OF COLOURED LIGHT UPON LIFE—PHOTOGRAPHY IN NATURAL COLOURS.

An Eye to Colour.—Dr. Henry H. Dor has presented to the Academy of Science and Literature of Lyons an interesting note upon colours and colour-blindness. The eminent oculist combats the theory of Mr. Gladstone and other scholars, that our ancestors were colour-blind, but he makes the extraordinary statement that persons who do not possess a knowledge of physics find much difficulty in distinguishing the colours of the rainbow, and only see in it three or four colours instead of seven. Colour-blindness, again, he says, must not be mistaken for disability to appreciate luminous intensity, for differences in intensity are apparent to those who have otherwise faulty eyesight. Thus a colour-blind photographer would, no doubt, be able to do his work perfectly well in spite of a lack of appreciation of certain tints. Recent investigations of the human eye have shown, indeed, how very little we really understand of this organ. Not long ago it was believed by many, at least, that our eyes saw simply because the retina or some other portion was set in vibration by waves of light striking the eye—that the eye, in fact, suffered vibration to a greater or less degree, and the colours we appreciated were in reality vibrations, and nothing more—that, in a word, our sense of sight was akin to that of sound. But the discovery of “visual-purple” in the eye—of a photographic film which is capable of being impressed in the same manner as the chloride of silver—has materially altered the views of the oculist. M. Boll, to whom, we believe, is due the discovery of this photographic action of the eye, has proved beyond a doubt that the “visual purple” plays a most important part in our organ of sight. It is a fine purple surface, which is continually freshened or resensitized by another organic film below. M. Boll has shown that the “visual purple” is capable of being impressed not only in life, but also in death, and our readers may remember his experiments with a rabbit's eye which were conducted in the presence of other learned physiologists. Possibly, colour-blindness, as it is called, may be due to some change or modification of this “visual purple” or photographic film, for there is little doubt that people do not always see tints with the same degree of intensity. Some experiments were made at Venice not long ago with coloured lanterns, which were set up upon the shore, and watched from boats on the water; the object was to see what colour was longest visible and the most distinctly seen. Thus, it was found that while some declared that they could see a green light, others avowed that it appeared white, until at a very long distance from shore one and all pronounced the green to be white. Red was visible as red longer than any other colour, but the lighter blues and greens were undistinguishable from white light at a certain distance. Thus in the case of green, colour-blindness at a distance is not an unusual circumstance, and this, perhaps, accounts for the fact that so many railway servants, when they are tested, are unable to pass the test as to colours; they know a red light and a white light when they see them, but the green at a distance looks like a pale white. The science of colours and colour blindness is one, therefore, upon which we have still to learn a great deal.

Gelatine Plates Abroad.—Gelatine plates form the subject of discussion at most of the foreign societies just now, but nearly all the experiences discussed have been secured with plates of English manufacture. Those of Messrs. Wratten and Wainwright, and Mr. Swan, Mr. Bennett, and Mr. Kennett, are the plates spoken of, and many are the expressions of surprise and astonishment at the sensitiveness of such plates. Nearly every beginner seems to make the mistake of not employing a proper dark room—

or, rather, a dark room properly lighted with ruby glass. Hence the films, when developed, generally show a fogged image. Once for all, beginners should understand that the ordinary orange glass is no safeguard against the fogging of gelatine plates, and the first thing to be done is to modify one's arrangements in this respect. Some photographers will not trust daylight at all, let it be ever so thoroughly filtered. They shut out every ray, and have recourse to a lighted caudle shaded by a ruby shade. Others, again, employ double casements of ruby and orange glass, so that they may be in a position to work the gelatine process at any time; while one gentleman we heard of, who has the advantage of a very spacious dark room, sets up a tent inside this that has a ruby window. Certain it is that one cannot work gelatine plates except in a modified light, while it is equally certain that photographers who undertake all sorts of work cannot afford to be without so sensitive a medium. If gelatine plates do not suppress the use of the silver dipping bath altogether, they will, assuredly, cause it to be less frequently employed, whether in the studio or out-of-doors. No one has such a love for the silver bath as to stick to it through thick and thin, and when it grows obstinate in very hot or very cold weather, it will be agreeable to know that its use can be dispensed with at any moment by employing gelatine plates. But, as we have said before, a thorough modification of one's dark room is absolutely necessary as a preliminary towards working the gelatine process with success.

Influence of Coloured Light upon Life.—Some further experiments appear to have been conducted in France upon the influence of coloured light upon animal life. It may be remembered that some time ago rose-coloured light was stated to be beneficial in the treatment of certain human diseases, and lunatics especially were found to be bettered in health by living under the influence of such light. We do not know how far these views were subsequently confirmed, but it is never well to accept the results of experiments of this kind too hastily. Some recent investigations that have been made with eggs and tadpoles do not add much to our knowledge in the matter. Flies' eggs are hatched more readily, it is said, under blue or violet light than under green. Frogs' eggs and the eggs of young trout are favourably influenced by violet rays, while next in order are blue, yellow, and white rays. Both red and green are reported in these experiments to have an injurious influence, and in the main the ordinary white rays are said to be the most beneficial to animal life, as they are, we know, for seedlings and plants. These are never so healthy as when grown under white light; they are heavier, and on burning yield more ash than when grown under the influence of coloured rays.

Photography in Natural Colours.—M. Cros appears to be still working at the problem of producing photographs in natural colours by the aid of three negatives produced of the same object under different conditions of lighting. He employs, it is said, three mediums in order to produce his three negatives, taking a picture of his object in the camera, first through a solution of nitrate of nickel, next through chloride of cobalt, and a third negative through bichromate of potash. In this way he gets three negatives, in which respectively the blue, yellow, and red rays have been cut off. To produce his pictures of the image in its natural colour, he makes three prints with his three negatives, employing respectively blue pigment tissue, red pigment tissue, and yellow pigment tissue. The three impressions (which should be transparent) when placed one above the other should yield the object in its pristine tints. However perfectly the analysis of the colours has been performed in the first instance by filtration through the three solutions we have mentioned, the subsequent synthesis, or building up of the tints afterwards, cannot be, as we have previously pointed out, but faulty in the extreme. It is impossible to secure

three pigment tissues of natural, unalloyed blue, yellow, and red; and as these are not true to nature, the resulting combination of the three cannot be true either. Neither, therefore, M. Cros or M. Ducos du Hauron, who is working on similar lines, is likely to achieve success, however nearly they may approach to it.

A FEW PRACTICAL ILLUSTRATIONS OF THE VALUE OF PHOTOGRAPHY IN LAW AND MEDICINE.*

BY ROBERT BIGGS, M.R.C.S.,
Deputy-Coroner for Somerset.

I AM sorry that the few desultory remarks I am about to make should have been dignified by our Honorary Secretary with the title of a "paper." Want of time during the last few months would have quite prevented my preparing a paper worthy of your acceptance, but taking Mr. Daniel's request as a very high compliment to one of this Society's youngest members, I venture upon a few "illustrations," the only interest of which lies in the fact that they are for the most part derived from *personal* experience.

I need not remind you that photography has a widely extended sphere of influence. In almost every department of art, science, literature, mechanics, and trade it has become a most useful auxiliary. In art, its reproductions of sculpture and painting have familiarized the multitude with the noblest creations of ancient and modern artists. By photography the colossal buildings of ancient Rome, with its architectural beauties; the temples of Greece; the still ancient, though more modern, cities of Europe, as Venice with its Bridge of Sighs, its "palace and its prison on each hand;" the Square of St. Mark, with its columns looking down upon the spectator with all the sad dignity of what it *has* been; the leaning tower of Pisa; the noble old cathedrals and churches of the Continent and of our own country, are all, thanks to this art, familiar even to the humblest student; and going back further still to the buried cities of Herculaneum and Pompeii, to the sacred ruins of Jerusalem, and to the lost magnificence of Nineveh or Troy; no sooner do they yield up their solemn secrets to the scholarly investigator, but this exquisite art steps in to reproduce for *all*, those beauties which would otherwise be limited to so few.

In science, again, what has it not done? In astronomy, thanks to Warren de la Rue, the map of the moon is almost as familiar to us as that of the earth. Its value in scientific investigation of eclipses of the sun has, under Captain Abney, become almost perfect. At the Greenwich Observatory it has been trained to register the daily and hourly aggregate of sunshine, with the variations of the barometer and thermometer, far more accurately than the most highly trained observer. In other branches of science it has given us much insight into the principles of each. It can render visible to our eyes the mysteries of the waves of sound or light, and which, without it, would much longer have remained *still* mysteries.

In literature it has given us to see each for himself specimens jealously guarded, and, indeed (generally speaking), utterly inaccessible. The Domesday Book, the rare originals of Shakespeare or of Chaucer, and valuable private and public historical records, are open to us all.

In mechanics, no important machinery ever leaves its factory till its form and appearance have been indelibly fixed, so that long after the machine itself has perished, its true resemblance still exists for future reference.

In trade and commerce still we find its use. You want a house: the agent sends you a photograph. You require a clerk, an assistant, or a secretary: you advertise "send carte." You hear of a horse or carriage, a chest of drawers,

or a drawing-room table: a photograph at a glance tells whether it is what you require. Nay, more, you want a wife: the *Matrimonial News* compels you to deposit your photograph, "not necessarily for publication, but merely as a guarantee of your good faith"; to show that you are not a base deceiver; that you are not imposing, under the pretence of youth and good looks, your grizzled locks and ugly features, on some poor simple maiden's innocence.

Now, the question arises, why is this? Why should photography thus supersede art? The answer is not far to seek. There are many reasons. First, its cheapness; second, its simplicity; third, its power of indefinite reproduction; and fourth, last, and most important of all, its absolute truth and fidelity. It *cannot* lie. It acts by the immutable laws of science, which are always the same—"which were, and are, and are to come." The aim and object of the painter is to make a *picture*; the object of photography is to *tell the truth*. As mathematics or logic is to poetry, so is photography to art. Each has its own sphere, and the sphere of each, we may be thankful, affords scope enough without either treaching upon the domain of the other.

What is there more pleasing to the eye than the beautiful creations of the painter? But yet they are for the most part *his* creations! They are in reality fiction founded upon fact; but still much of their beauty is *fiction*. No portrait painter could live by his art, and very little pleasure could be derived by looking at his works, if he adhered strictly to the literal truth; but so long as he merely uses his art to heighten any excellences which may exist, and soften asperities, while retaining that *vraisemblance* which is his main object, no one complains; but on the contrary, they can the more highly recognize his genius, just as when we read a parliamentary debate we know that the effect of the speeches being properly and fairly given, how much of the pleasure we derive is due to the skill of the reporters, by whom rugged and broken sentences are worked into a smooth and harmonious oration.

But, as I have said, valuable as all this addition and decoration may be, there are cases in which, for special purposes, it is utterly inadmissible, and of these special purposes in the two professions of Law and Medicine it is essential that everything else should be sacrificed to *truth*: plain and unembellished truth. As evidence must be given the truth, the whole truth, and nothing but the truth, and here the lens and camera are unimpeachable witnesses: they are, indeed, the only ones upon whom cross-examination is always futile; and silent witnesses as they are, they speak more forcibly to a jury than the most silver-tongued eloquence of counsel, or the most impressive charge of the judge, because the truth as told by photography is not only truth, but *unbiassed* and *unprejudiced* truth. No "fear, favour, or affection" can influence *its* testimony, and no threat or promise of reward can make it vary in its statements; and when our great poet Tennyson tells us that "the lie which is half a truth is the basest of lies," this witness at least is one which will never incur the odium of such a charge.

I should make these remarks far too long were I to bring forward the cases in which portraits obtained by photography had been given in evidence, or even scenes of buildings and localities. These are matters of everyday occurrence, and you are all familiar with them. I would, however, just allude to the great value of photography in the reproduction of letters and documents, by which it is easy, as in a great trial a few years ago, to give the jury a copy of an immense mass of documents, which would otherwise have had, at an enormous waste of time, to have been handed round to them separately for inspection, examination, comparison, and which was entirely obviated by means of photography; and it is with reference to this use of it in copying writing that my first personal illustration is given.

* Read before the Bristol and West of England Amateur Photographic Association.

At a serious railway accident, a few years ago, a question, which may have been a most important one, turned upon an entry made in the signalman's book. An examination of this book showed a suspicious appearance, and led to a discussion whether it had been tampered with by erasing a figure and substituting another; but the jury were quite unable to agree on the subject, some of them expressing an opinion that it had, and others that it had *not*, been interfered with since the original entry had been made. I had my own opinion on the subject, which I had, of course, no right to express; but during the few days of adjournment I had a part of the page not only photographed, but enlarged. This is the copy so made, and I think you will see, on careful inspection, that it proves unmistakably the fact that there had been erasure and subsequent entry of different figures [*photograph shown*].

The next case I shall mention is also connected with another railway accident, which involved the death of a large number of people, and this also was a case in which I obtained a magnified copy of the entry in the signal book. I have, unfortunately, mislaid this specimen, which not only proved the fraud, but showed precisely the manner in which it had been perpetrated.

The next illustration I have to offer is the accompanying picture. You will readily see that it makes no pretensions to be a work of art; it is altogether, perhaps, as hideous and repulsive as a photograph can be. It is, indeed, a ghastly object, and a ghastly and painful history is attached to it.

In April, 1874, I was called on, in the discharge of my duties as Deputy-Coroner of this division, to hold an inquest on the body of a female child found in a field at Totterdown, near this city. Cases of this kind occurring in newly-born children are, I regret to say, far from uncommon, and generally speaking are most difficult, indeed, generally impossible, of detection; but this case was altogether exceptional. It was not new-born, but a child of three or four years old; its frame frightfully emaciated, and it appeared to have been doubled up and tightly compressed so as to be packed into a small compass for conveyance in a carpet bag or similar vehicle. The result of the post mortem examination was absolute proof that the poor child had been starved to death; no trace of food could be found in the whole tract of intestines, and it was proved almost conclusively that nothing whatever could have entered its lips for many days prior to its death. At first there was a strong opinion among the jury that this horrible crime had been perpetrated a long distance away; but on consideration I thought this very improbable, because of the weight and size of the body, and the difficulties and risk of travelling with it. It seemed to me more probable that such a hideous burden would be got rid of as quickly as possible, and I hazarded the opinion that the guilty parties (if detected at all) would be found within a dozen miles of the spot where the body was found, viz., either in Bristol or Bath. The features of the child were distinctly marked, and of a peculiar expression, and I arranged with the police to have the body photographed before burial, and this was done by the then photographer to the Bristol Gaol, and meanwhile diligent investigation was carried on in Bristol by Sergeant Dewey of the County Police, and in Bath by Detective Berry of the Bath force. Three or four weeks after the inquest the latter called on me to borrow the photograph, and the next day he arrested a woman who turned out to be the mother of the child. He had shown the photograph now before you to several persons, who had each instantly recognised it as that of the prisoner's child. Ample evidence was obtained to prove that death had occurred from systematic starvation by the mother without the excuse of want, and that her deliberate intention was to get rid of a burden which was a tax and encumbrance. She was tried and convicted at the ensuing Assizes before Lord Coleridge, who, in sentencing her to death, used language which held out no hope that her life would

be spared; but the accumulated horrors of her crime, and its detection, with the anxiety of her trial and conviction, and, let us hope, the sting of conscience and the pangs of remorse, were too much for the wretched woman. Her mind gave way on the day of her conviction, and her life hung on a thread for several weeks. The capital sentence was commuted, and she is now undergoing confinement for life as a criminal lunatic. In this case there can be no doubt that the discovery of a horrible crime and detection of its perpetrator was due to the melancholy picture now in your hands.

As in Law, so in Medicine, scrupulous fidelity of illustration is required: not that I am undervaluing the skill of the artist, to whom, indeed, the profession owe much more than I can acknowledge. Those who have seen modern anatomical works must know that the highest skill of the highest men has been bestowed upon this subject; but still there are many matters in medical science where such aid is inadmissible or unobtainable. As a matter of simply retaining a visible record of a case, this art is most valuable and useful, and I show you the accompanying as specimens of remarkable cases in which I have been able to avail myself of it [*here the speaker exhibited a number of photographs strikingly illustrating his remarks*].

I have been favoured with some beautiful specimens bearing on this subject by the Woodbury Company, and while gratefully acknowledging their kindness in the matter, I would take the opportunity of saying that if anything could add to the value of photography in its varied uses, it would be the fact of its faithful reproductions by this process. Perhaps the highest compliment I can pay it is to say that I had intended to show a book this evening as a specimen of one illustrated by silver prints, believing that the pictures had all been printed off from the negative, till, among the specimens sent me by the Company, I found these identical illustrations, which proved them to have been executed by the Woodbury process. The large number of books illustrated by this process are sufficient evidence of its appreciation for purposes of illustration.

Now among these specimens are two cases of strabismus or squint, taken before and after operation. Had these been merely drawings we may fairly have considered that there was some little exaggeration—either that the deformity or the cure had been too highly coloured; but knowing the veracity of our witness, we are satisfied that this is not the case, and we can more highly appreciate the skill which has wrought so great a transformation.

Again, some time ago an American surgeon devised a new mode of treatment in the disease known as spinal curvature. He published the details of his treatment and the description of his apparatus, but, to make his description more clear, his work was illustrated by photographs reproduced by Woodburytype, showing the steps of his manipulation in its various stages, and rendering the whole so clear that any medical man could adopt the plan who had never seen or heard of it previously.

Here again, from these Woodburytypes, I select another specimen where photography takes a place denied to art [*photograph on General Paralysis exhibited*].

I could go on and weary you with illustrations. I could point out to you that by selections of patients in lunatic asylums most valuable records showing the *types* of insanity have been collected, and there is little doubt that by diligent study of these and other "types" a broad foundation is being laid towards a classification of cases far superior to those hitherto available. Another step in a somewhat similar direction is being made by the Anthropological Society, who are endeavouring to collect photographs of the typical races of the British Empire.

I will not trespass longer on your attention, although these matters may well deserve special attention on some future occasion; but I hope the instances I have adduced are sufficient to show you that this beautiful and fascinating art not only subserves to the amusement of its

disciples, but that it has a far higher aim in the infinitude of its applications, and we may have the high satisfaction of knowing that, amateurs as we are, it is to amateurs that most of the improvements and discoveries of photography are due, and that there is not one of us who, practising it with the simple qualifications of readiness to learn and equal readiness to teach, but must add at least one stone to the magnificent structure built for us by our predecessors.

THE METRIC SYSTEM.

BY HENRY M. MINTIRE, M.E., A.C.

THE base of the system, the metre, was intended to be one ten-millionth part of a quadrant of the earth's circumference. The true length is preserved upon a platinum bar, the original of which is kept in the archives of the French Government. This is divided into tenths, hundredths, and thousandths, each grade being indicated by prefixing to metre either *deci*, *centi*, or *milli*, as the case may be. It is increased, also, on grades of ten, one hundred, one thousand, and ten thousand, these being indicated by the prefixes *deca*, *hecto*, *kilo*, and *myria*. A square, whose side measures one-tenth of a metre or decimetre, was taken as the unit for the measuring surface, and called an *are*; this was divided and increased in various grades by ten, in the same way as the metre, and named in the same way. A cube whose edge measures one metre was taken as the unit of solids, called a *stere*, and treated in the same way as the *metre* and *are*. A hollow tube, whose inner edges measure one decimetre was taken as the unit for measuring liquids, and called a *litre*. The weight in a vacuum of the amount of water which would just fill a hollow tube, whose edge measures one centimetre, when at its greatest density (at 40° Cent. or 39.2° Fahr.), is taken as the unit of weight and called a *gram*. All this is well known, and shows how nicely the entire system is built up from the unit of length. Its greatest fault is not so much its fault as its misfortune. The greatest objection has not so much to do with any inherent failure of the system as with difficulty in its introduction. In France and Germany this has been accomplished; also, in the whole scientific world; but in the practical, the case is different. Unfortunately or fortunately, photography, like Mr. Gradgrind, being "eminently practical," has never (in this country) felt the benefits of the system. But the benefits never having been experienced, the loss is not known. One source of inconvenience, however, continually arises. The metric system being in use by many photographers on the other side of the Atlantic, their formulæ are given in this system, and on account of this the difficulty arises. There are two ways of avoiding it, however: either to make use of the metric system, or by multiplication and division convert that system into your own. Let us glance at each of these, beginning with the better, more sensible, and easier—by making use of the metric system.

The actual using of the system is not as difficult to obtain as is generally supposed. It, however, resembles a foreign language in one respect. A person, to use it fluently, must, so to speak, think in it. That is, thus, for example, a person learning German will never become proficient as long as he expresses what he wishes to say in English, and with a dictionary in his right hand and a grammar in his left does it into German; but he must think and express his thoughts in the German with no reference to his mother tongue. So in the metric system if a person wishes to obtain an idea of, say the amount of ten litres, and to do so first thinks that one litre is about nine-tenths of a quart, hence ten litres are about nine quarts, and thus obtains his idea, will never succeed. On the metric system, he must think of a litre as a litre, with no reference to anything else. And this is the easiest thing in the world to do. If a person arms himself with a metric rule, a set of gram weights, a litre measure, and a centigrade thermometer, without any trouble, and almost before he knows it, he will have the metric system at his

finger ends. The entire system, as mentioned in brief above, and as generally learned, is scarcely ever met with; though, for example, one will hardly ever see the *are* or *stere* mentioned; but for square measure, square metres (S. M.) or fractions of them, are generally used; and for solid measure, cubic metres (C. M.). The litre is often used, but fractions of it are generally expressed in cubic centimetres (C. C. or C. C. M.) of which it will be remembered that it takes one thousand to make a litre. But if, on the other hand, a person wishes to convert the metric to our system, he can easily do so by multiplying the metre by 39.37, which will give him the result in inches; the gram by 15.4, which will give grains; the litre by 0.9, which will give quarts; the cubic centimetre by .035, which will give fluid ounces. Of these methods, the former is always to be recommended. A set of gram weights, a litre measure (or a 500, 250, 100, 50, or 40 cubic centimetric measure, as one may wish and care to pay for), and a metric rule, are all cheap, and easily obtained. Then, all trouble of multiplying and dividing, and all chances of error from so doing, are avoided.

There is no trouble to learn to use them; a person who can use any weights and measures, can certainly use these. Then, without trouble, or even thought of it, he learns the metric system perfectly.

One other thing—he is helping along a good cause; he is making the universal use of this system a consummation of the near future; for, although no one at present living may live to see it, "it's coming yet for a' that, that man to man, the world o'er, shall 'use the metric system for a' that." The period of transition is the one of trouble. Still, if met fairly and squarely, the worst is soon over.

The initiative has been made, and the good work will be slowly carried on. . . . Blessed will that man be who will have a vivid idea of the length of a metre, and a slight and indefinite opinion in regard to the yard.—*Practical Photographer Almanac*.

REACTIONS OF THE CHROMIUM ACIDS AND CHROMATES ON ORGANIC BODIES.

BY DR. J. M. EDER.*

As regards the use of *albumen* in chromate photography, the author points out that an aqueous solution of that substance is coagulated by chromic acid, but with potassium bichromate a chrome alum undergoes no change. Albumenized paper, rendered insoluble by heat or by alcohol, has often been employed as transfer paper instead of gelatinic paper made insoluble by alum. Photo-lithographic transfer paper is also sometimes coated with coagulated albumen before it is covered with the regular sensitive film. The albumino-chromate is very sensitive to light, though not in so high a degree as gelatino-chromate; it turns brown on exposure, and becomes insoluble in water. A sheet of paper coated with albumino-chromate, exposed under a negative, and then blackened with printer's ink, turns white in the parts not acted on by light when treated with water.

For photographic purposes, albumen freshly prepared from hens' eggs is the best; but when economy and convenience are objects, the commercial solid albumen may be used with advantage. As a guide, the author lays down that an egg contains about twenty-five grammes of white, and seventeen grammes of yolk. To obtain from solid albumen a fluid of the same kind as the fresh white of an egg, one part of weight of that substance must be dissolved in from six to eight parts of water. Unfortunately, commercial albumen is often adulterated with gum and dextrine, which are not easily detected, as they dissolve in water. If, however, the percentage of these substances be small, they will not injuriously affect the photographic process. The best analytical process for testing albumen is to mix a twenty per cent. solution of that substance with an equally concentrated boiling solu-

* Concluded from p. 101.

tion of alum, and to filter and weigh the precipitate. An albumen which leaves only a small residue can be used for photography without hesitation. Pure albumen obtained from blood, which is often sold in the solid state, can be used without disadvantage, either mixed with white of egg or alone.

Chromated albumen, after exposure, is more resistant than gum-arabic, and films of the same substance possess the advantage over gelatine of being developable in cold water, on which account they are employed by preference for transfer papers. Photo-lithographic transfer papers prepared with gelatino-chromate do not give such fine, clean pictures on the stone as those prepared with albumen. But a mixture of albumen and potassium bichromate cannot be used for thicker films on glass, as it cracks in drying. Albumen sensitized with a chromate becomes spontaneously insoluble after lying for a few days in the dark; a paper prepared with albumino-chromate cannot be depended on except when recently made. An aqueous solution of albumen mixed with one of the double chromate of ammonium and potassium remains for a long time sensitive to light, provided it be kept in the dark and protected from decomposition by a few drops of carbolic acid. Solid albumen dissolves very quickly in a concentrated solution of ammonium chromate, and albumenized paper that is to be sensitized in such a solution must be floated film upwards on the bath; in this respect the albumen paper is made more delicate than gelatine paper.

In the collotype process, when a substratum is required, it is usual to make it of a mixture of gelatine and albumen, in order to cause the upper film to adhere to the glass; but the actual printing layer of colloid ought not to contain albumen, as the addition of that substance makes it less capable of resistance to mechanical pressure. Gelatine to which albumen has been added is less soluble in water, and the mixture is now not so much employed as formerly. The action of light on a mixture of albumen and potassium bichromate can scarcely be exclusively referred to a secondary action of chromium oxide, for the latter does not render albumen insoluble. It is probable that in this case the production of the image depends on a higher degree of oxidation of the albumen (there are numerous instances of derivatives of this kind) in combination either with chromium oxide or with the albumen itself; more approximately correct analytical details can hardly be obtained, considering the very complicated composition of albumen.

Glycerine is much used as an adjunct in chromate photography. This substance, when sensitized with potassium bichromate, turns brown on exposure to light, but loses some of its stickiness. It can be used for the carbon process, but the pictures produced are not nearly so permanent as those in gelatine. No use is therefore made of the sensitiveness to light of glycerino-chromate, especially as it is very slight in comparison with that of gelatino-chromate—so much so that in a mixture of gelatine, glycerine, and chromate, the second of these substances remains unchanged, and appears to act only mechanically. On the other hand, advantage is greatly taken of the property which glycerine possesses of rendering gelatine flexible and elastic. Printer's rollers are made of such a mixture; glycerine is added to gelatine to make elastic the pellicles for removing collodion from glass plates, and to increase the flexibility and solubility of the gelatine film of carbon paper. The addition of glycerine in the case of carbon paper is not, however, adopted by all photographers, for it tends to make the film too soluble, so that it will melt when the temperature is at all high, and it gives harder pictures than when soap or sugar is mixed with the gelatine.

Glycerine has been used in the dusting-on process to increase the hygroscopic quality of gum-arabic. A dilute solution in water is also recommended for wetting collotype plates before rolling. This solution does not soon dry, and in hot weather increases the hardness and durability of the gelatine layer. A mixture of diluted glycerine

and soluble salts is used for keeping moist collotype plates under the steam press. Some authorities suggest the addition of glycerine to photo-lithographic transfer paper, and also to photo-collotype plates, which are developed cold by acetic acid. The author disapproves of glycerine as an adjunct to the gelatine layer of a collotype plate, because it renders the latter brittle. In photo-electrotype he found its employment advantageous, because it increases the solubility of the gelatine, and promotes the complete development of the image in hot water. He prefers, however, cane sugar, for it permits the film to dry quicker, is still more favourable to development, and brings out better all the fine lines. It must be borne in mind that a gelatine containing too large a proportion of glycerine will be no longer sensitive.

The author next describes his experiments with casein. He obtained a solution of that substance in ammonia, sensitized it with potassium bichromate, and coated a plate with it. On exposure, the film turned brown, but the image was developed with difficulty. The incompleteness of the development and the defectiveness of the image convinced him that casein could not be used with effect in chromate photography. For coating transfer paper for carbon printing, an ammoniacal solution of casein may be used with advantage; but, in the opinion of the author, transfer paper of this kind is not likely to supersede the more convenient methods now in use. The employment of a mixture of starch and chromate in the preparation of photo-lithographic transfer paper has also been recommended, but has met with no adherents.

With regard to the resins, the properties of which the author also investigated, he found the only ones at all suited for experimental purposes to be colophony or common resin and shellac. Of the first of these he obtained a solution in ammonia, added potassium bichromate to it, and let it evaporate in the dark on a glass plate, so as to produce a film. This film, which was very uneven, he then exposed to the light under the negative of a linear drawing. No change was visible in the film even after the lapse of some days, and developing with dilute solution of ammonia or spirits of wine dissolved the whole film, so that no image was produced. This experiment tends to prove that the resins alone are of no kind of use for chromate photography; but, mixed with other substances that are sensitive to light, they can be used to some advantage. A small quantity of resin introduced into the gelatino-chromate tends to make the latter less easily soluble, and the addition of an alcoholic solution of resin to the gelatine in the collotype process renders the plate better able to withstand mechanical pressure. However, at the present time, such adjuncts to collotypes as gelatine are no longer employed, as the same effect can be obtained by simpler means.

The author concludes his very exhaustive treatise in the following words:—"In the above-described investigation on the reaction of the chromates in relation to photography, I have dealt first of all and at greatest length with gelatine. In this I was guided no less by the conviction that that substance is the most important in this relation, than by the fact that with it the reactions are the most complicated, while, at the same time, the peculiarities that characterize it are common also to gum, albumen, and other substances of the same kind. The course of the chemical reactions is not subject to any great vicissitude, but the intensity of the action of the chromates on different organic bodies depends much on the nature of the surrounding circumstances; the phenomena of reduction often make their appearance undesirable in degree, and at unseasonable times. Only an accurate knowledge of all these emergencies will place chromate photography in the position of a reliable process; a rational insight into the essence of the method must enlarge its sphere of action, and then the chromate processes will inaugurate for photography a new era, in which they will maintain a brilliant position."

IN MEMORIAM—R. T. CRAWSHAY.

We record with deep regret the death of a gentleman who held a very high position in the ranks of amateur photographers—Mr. Robert Thompson Crawshaw, of Cyfarthfa Castle, Glamorganshire, who died on Saturday at Cheltenham. Mr. Crawshaw was for many years an enthusiastic and successful amateur photographer, his portrait and genre studies being very familiar for many years past in the Exhibitions of the Photographic Society. A few years ago he became impressed with the idea that large or life-size portraiture had never received sufficient attention amongst photographers. He ordered specially constructed lenses of Mr. Dallmeyer for producing such portraits direct, and devoted his attention to such work with considerable success. He then offered a series of prizes for the best life-size pictures, both enlargements and from negatives produced direct, the competing pictures being hung in the Photographic Society's exhibition. In subsequent years he offered further munificent prizes as encouragement to specific effort in photography. During the last few years his own contributions to the Photographic Exhibition have consisted chiefly of landscapes, their pictorial excellence generally placing them amongst the most artistic pictures exhibited.

For many years photography was to Mr. Crawshaw a solace in the isolation produced by total deafness. He pursued his favourite occupation with equal earnestness and fine taste, producing as much good work as many a successful professional photographer working hard for commercial purposes. Although debarred by his unfortunate aural disabilities from attending photographic meetings or taking part in the public life of the photographic community, Mr. Crawshaw was interested in its movements, and for many years past entertained every spring as guests a number of the most distinguished amongst photographers.

As a public man, Mr. Crawshaw was commonly known as the "Iron King" of Wales, being the proprietor of the immense iron works at Cyfarthfa, where, for upwards of a quarter of a century, he held a kindly, patriarchal sway, the rupture of which by the great strike in South Wales was a grief rather than a pecuniary loss to him, as some of his works had for some time been kept open at a loss rather than dismiss his men. During the last two or three years Mr. Crawshaw's health has been failing, and his death on Saturday removes him in his sixty-third year.

REFORM IN WEIGHTS AND MEASURES.

On the first day of the present year an Act of Parliament came into force giving legitimacy to what is known as the metric system of weights and measures. This legiti-

macy did not enforce the system, but gave a permissive sanction to its use: sales made by such a system instead of what is known as "imperial" measurement became legal. Amongst scientific men the superiority of the metric system has long been acknowledged, but custom and prejudice are strong, and very many years will probably elapse before the change is effected in this country. In France, where it originated, it was one of the outcomes of a complete convulsion, rather than the result of a deliberate estimate of its superiority.

In the terrible upheaval of the framework not only of government, but of social life, which occurred at the French Revolution, there was an insane desire to change everything which had an established existence. A system of weights and measures which had existed under sanction of government must be bad, and must be superseded. Fortunately the system devised was not characterized by the insanity of the period; and the metric system, a plan simple and symmetrical, was devised and adopted. It has become the system of science all over the world, and is worth a little trouble to comprehend and use. All the formulæ which reach us from Continental savans are stated in metrical terms, which terms should be commonly understood and used by photographers. It is not an uncommon thing for us to receive requests from correspondents asking for the translation of some special formula from metrical to imperial terms. It has been also not unfrequently suggested to us that in giving articles and formulæ from Continental journals, we should reduce the metrical terms of the writers to the common terms of imperial weight and measure used in this country. We have, for many reasons which we have explained, and which it is not now necessary to repeat, held it to be wiser to repeat such formulæ in the terms of the original authors, leaving the reader to work it into his own figures. By constant repetition in our pages it becomes familiar to readers, and any trouble incident upon novelty and strangeness soon disappears. A curious illustration of the wisdom of the course we elected to follow, from another point of view, has just come under our attention. The translation and reproduction of articles from foreign journals is at times effected under pressure. If an interesting novelty appears it is translated, and reproduced without delay. In change of the denomination of figures, effected in haste, there is much liability to error. A case in point occurs. In a recent American translation of the kind, the metrical terminology is changed into the familiar figures, and in every quantity there is more or less of error, in some cases to a very serious extent, altogether invalidating the formulæ. Of course such error is not readily excusable; but the conditions render it possible, and may as well be avoided. If the reader have the original terms to refer to, if he have made a blunder in modifying quantities, he can easily correct himself. This is but one trifling addition to various good reasons why photographers should become familiar with the system used by scientific men all over the world. On another page we reprint from an American contemporary an interesting article on the subject to which we commend attention, and we append some tables for conversion of metric into imperial terms.

PHOTOGRAPHY AT THE ROYAL CORNWALL POLYTECHNIC SOCIETY.

THE forty-seventh Annual Exhibition in connection with this Society will be held at Falmouth in August next, opening on Tuesday, the twenty-sixth of that month. Prizes are offered to photographers for landscapes, for portraits, for portraits untouched, for composition pictures, for instantaneous pictures, for dry plate pictures, for pictures by improved processes, for enlargements.

Medals are offered also for improved apparatus and appliances, including magic lantern work.

All exhibits must be accompanied by a written explanation of their specialities.

Intending contributors desiring information regarding the photographic department may obtain details by applying to Mr. W. Brooks, of Warren Road, Reigate, who, being greatly interested in this exhibition, has kindly undertaken to aid the photographic department. We subjoin an extract from the programme :—

MEDALS AND PRIZES.

REGULATIONS FOR COMPETITION, ETC.

Competitors are divided into four classes.

1.—The First Class consists of members of the Society; also of persons who pay 3s. to be allowed to compete for prizes. First Class competitors are entitled to admission on the first day of the Exhibition, after twelve o'clock.

2.—The Second Class consists of persons of the working order.

3.—The Third Class consists of schools for the higher branches of education.

4.—The Fourth Class consists of schools for the children of the working orders.

5.—The Second, Third, and Fourth Classes may compete for Prizes without any subscription, but are not entitled to free admission to the Exhibition.

6.—No person shall be entitled to a prize for any article which has appeared at a previous Exhibition of the Society, unless exhibiting some improvement.

7.—In the Department of Fine Arts, Professional and Amateur Artists must state whether their productions are original or copies.

8.—The Judges are empowered to award Prizes in money to the extent of £1 only, except in the case of Special Premiums. When medals are awarded, the converting them into money,

according to the following scale, shall be at the discretion of the Committee :—

First silver medal	£5 0 0
Second ditto	3 10 0
First bronze medal	2 0 0
Second ditto	1 5 0

9.—Medals only (not convertible into money) can be awarded to patented or registered articles.

10.—No competitor may receive more than one medal or prize in the same department in the same Exhibition. (This regulation does not apply to mechanical or scientific inventions, or to photography.)

11.—No holder of a medal or prize may receive a prize of the same or a lower value for similar subjects in the same department at the next two subsequent Exhibitions; but the Judges will be empowered to give certificates of merit to persons excluded by this rule.

12.—The carriage of all articles sent to the Exhibition must be prepaid, unless permission to the contrary has been previously obtained from the Secretary. Pictures and other works of art may, however, be sent free under certain regulations to be learnt of the Secretary.

13.—All awards are at the discretion of the Judges, and none will be made if no article be deemed of sufficient merit.

14.—All articles intended for exhibition must be delivered at the Polytechnic Hall, Falmouth, one week before the opening of the Exhibition, or they will not be eligible for competition.

15.—No article exhibited can be removed from the Hall, before the close of the Exhibition, without the consent of the Secretary.

16.—The Society is not responsible for loss of, or injury to, any article sent for exhibition.

* * Information respecting the Society and the Exhibition, and forms to be filled up by the exhibitors, may be obtained from the Secretary, EDWARD KITTO, Polytechnic Hall, Falmouth. Information respecting the Art Union may be obtained from the Honorary Secretary, R. J. BEVIL SHARPE, Falmouth.

FRENCH CORRESPONDENCE.

FIRST GENERAL MEETING OF THE PHOTOGRAPHIC UNION OF FRANCE—APPLICATION OF THE PAPIER-ARTIGUE TO IMPRESSIONS IN FATTY INKS—PROCESS OF M. GERMEUIL-BONNAUD—THE MONUMENT TO NICEPHORE NIEPCE—PROPOSAL FOR A MONUMENT TO DAGUERRE.

First General Meeting of the Photographic Union of France.—The first general meeting of the Union Photographique de la France was held on Wednesday, the 7th of May last. A report was read by the chairman on the details of the organization of the Society. The numerous and important questions raised by these details had compelled the committee to call the meeting a month later than had been at first intended. Henceforward it was hoped the regular meetings of the Union will be held on the first Wednesday in each quarter, in accordance with the terms of the statutes of the Society. In announcing the names of those who had joined the Union, the executive committee urged strongly upon all the members who had not sent in their admission certificate to do so without delay. Of the foreign members who had already been admitted members of the Society, the announcement of two names was received with every sign of lively satisfaction; they were those of M. Carlos Relvas, of Collega, in Portugal, and of M. Lewitzsky, of St. Petersburg. The applause with which these names were received was perfectly well-deserved. M. Carlos Relvas is an eminent amateur, who has not only produced important works in all the different branches of photography, but has on every occasion given evidence of his hearty and generous co-operation with all institutions which have for object the development and progress of our art. M. Lewitzsky is a skilful operator who distinguished himself by the position he took up when Vice-President of the Jury at the last International Exhibition at Paris; he is also a photographer in special favour with all his fellow-workers. It will be recollected that the Photographic Union of France, when it was first constituted, presented

him with a congratulatory address (see PHOTOGRAPHIC NEWS for the 28th February, page 102). M. Lewitzky has replied to this address in a letter full of feeling and sincerity. He informs the young Association that his report on the late Exhibition is in the press; if, after having read this report, the members confirm their address, he shall regard their good wishes in the light of a great honour, and more especially of a moral support of the opinions which he defends. "The first part of my report," M. Lewitzky says in this letter, "treats of the negative processes, particularly in portraiture. It contains a reiterated avowal of my profession of faith, which, unfortunately, was not found to be in accord with the decisions of the jury. I do not protest, for all deprecation is now useless and might be misunderstood; but I reassert the variations, and confirm the mistakes, that were made, as well as point out their cause. It is the entire absence of any principle on which the decision ought to be founded that made the awards appear arbitrary, and tends to render photography the laughing-stock among the professed arts. My aim was and is to bring photography into harmony with art, to save it from the state of decay into which it has fallen in France, thanks to a spurious patronage which seeks to divorce it from art, and for private purposes to completely dominate it. It is not in France, the home of the beautiful, the true, and the just, that so pitiful a rôle as this should be permitted to be played." Of course these eloquent words were received with the greatest applause by a body of men whose ideas they so well expressed.

Application of the Papier Artique to Printing with Fatty Inks.—On the agenda paper of the same meeting were entered several new inventions to be submitted to the Society; among them the *Chromographe*, the apparatus for working the process *Polychrom-autographique*, by M. Holtzmann, of Paris, and the method of reproduction by means of a layer of aniline, by M. Bauer, of Vienna, all of which I have already described for the benefit of the readers of the PHOTOGRAPHIC NEWS. M. Artigue showed some of the results obtained with the paper of his invention, and gave a most interesting account of an application of it to his system of photo-tracing. He passed round some specimens which show that a negative obtained from his special ink and sensitized paper can be used for transferring to zinc or stone to serve as a printing surface with fatty inks. As the inventor has not yet taken out a patent for his discovery, he was unable to explain the process, but he promised to make it known to those who applied to him for the special fittings required for working it.

Process of M. Germeuil-Bonnaud.—The meeting was also attended by M. Pellet, who communicated the results of the last improvements that he has introduced into his *Cyanofé* paper, and by M. Germeuil-Bonnaud, who exhibited to his fellow-members numerous samples of his photography in colours. It is no easy matter to obtain for a new photographic process the unanimous approval of a meeting exclusively composed of professional photographers, who are generally sceptical in the matter of the difficult question of colours. M. Germeuil-Bonnaud submitted some admirable reproductions in portraiture and landscape, as well as of flower painting and art objects. He was congratulated on all sides, and it was generally acknowledged that up to the present no more genuine or valuable means of obtaining colours in photographs had been introduced to public notice, *en attendant* the long-desired moment when they shall be produced directly in the camera.

Monument to Nicéphore Niepce.—The next subject on the agenda paper of this meeting was the question of a subscription in aid of a statue of Nicéphore Niepce. On this subject there arose a most interesting discussion, in the course of which the following points were very clearly established:—1. That the memory of Nicéphore Niepce is incontestably entitled to a monument; 2. That the com-

mittee at Chalons, the cradle of Niepce, to whom the proposal for a subscription is due, had gone out of the way to insult the memory of Daguerre; 3. That a statue of Daguerre ought also to be erected at Honfleur. The discussion, while bringing out plainly the feelings of sympathy with which the members of the Photographic Union of France welcomed the proposal for raising a memorial in honour of Niepce, nevertheless accentuated the inopportune and reckless partiality of the Chalons committee. This committee was extremely ill-advised to imagine that the success of its appeal depended on the amount of discredit that could be thrown on the merits of Daguerre. Great astonishment was expressed at this meeting of the Union that, although the appeal has now been for nearly a year before the public, no voice has yet been raised in protest against such an unfair and almost unprecedented procedure. In fact, it has never before this been pretended that in order to erect one monument it is absolutely necessary to pull down another. The party spirit manifested against Daguerre, who has never hitherto, so far as I know, been accused of being a usurper, was universally disapproved; and the inauspicious appeal, showing so plainly a petty provincial spirit, did not meet with a single advocate at the Photographic Union of France. It was asked why Nicéphore Niepce should have taken Daguerre as a partner if his assistance were not indispensable. There can be no doubt that Niepce was the first to hit on the idea of bending light to his service, but he has himself acknowledged that without the aid of Daguerre he would never have realized a success with the bitumen of Judæa alone, which formed the groundwork of his invention. Besides, as is well known, in every age there are men occupied simultaneously in working out an application of the same phenomenon. Often they have published the results of inquiries at the same moment; and at each time a great discovery has amazed the world, more than one inventor starts up and claims priority in it. The reason is that the discovery which meets a general want has long been sought for, and was, for some time, so to say, "in the air." This was undoubtedly the case with photography; but why, then, is it necessary, under the pretence of appealing for subscriptions, to draw up a bill of indictment like the following:— "Time has silenced the falsehood, born of an intrigue, which retarded the apotheosis of Niepce. Possessing the modesty and disinterestedness natural to real worth, when he had discovered the principles of his invention, he still hesitated, conscientiously, to publish it, and to claim the merit for himself, while in its original imperfect state. He waited to perfect it before divulging it, and he was working at it with his habitual patience when death overtook him. Then it was that an artist, the manager of a diorama, who, three years previously, had got scent of Niepce's work, and robbed him of the secret of his process, who since that time had been connected with him in the name of partner, and had been occupied in perfecting the secondary details of the process, astutely claimed for this subordinate work the merit of a recondit investigation, resulting in a personal discovery. . . ." These are the very words which the committee of Chalons-sur-Saône do not hesitate to employ. By what right, it is asked, do they pronounce so severe a judgment, before any one has made a charge against the accused? Where is the evidence and where the *corpus delicti* on which he is condemned? Why do you constitute yourselves a court of honour before any one has asked you to undertake that office? You wish to get a statue, but you could surely obtain it without distorting history after your own fashion. It is true the committee are able to produce a deed of partnership entered into between Daguerre and Niepce in the month of March, 1830, and according to them this is quite enough to convict the former. But the first paragraph of this deed suffices to overthrow the charge: here it is:—"Article 1.—A partnership is hereby established between MM. Niepce and Daguerre,

under the commercial title of Niepce and Daguerre, for working out the said invention, which has been invented by M. Niepce and improved by M. Daguerre." It is possible that Daguerre was in the wrong to give his own name alone to the process of Daguerreotype, but it will be acknowledged that it would have been impossible to combine the two names; "Niepce-Daguerreotype" would have grated still more harshly on the ear. Then, again, why did not Niepce's son, who continued in partnership with Daguerre after his father's death, complain of the name given to the invention, and protest against the robbery? Listen to what the Chalons committee say on this point:—"The son, when he authorised the partner of his late father to claim the merit of the discovery for himself, was bound by an agreement wrung from him by his indignance, both material and mental." But to call Daguerre "the parasite of Niepce's genius" is hardly the way to prove the charge of having usurped a title which Niepce's heir had sanctioned.

Proposal for a Monument to Daguerre.—All these points were fully discussed at the meeting, and the discussion was illustrated by many anecdotes of both inventors. It concluded with a motion protesting against the terms of the Niepce committee's circular, and that a letter be written to the municipality of Honfleur, Daguerre's birthplace, asking them to raise a subscription for a monument to Daguerre. This proposition was unanimously carried amidst the applause of the meeting. With this action of the Photographic Union everyone will no doubt be satisfied—with the exception, perhaps, of the Chalons committee, who can scarcely be expected to express their gratification. Historic truth will be vindicated, or rather will be found to be capable of making itself respected; tardy justice will be done to the memory of an eminent inventor, at the same time that a like honour is conferred on one without whom the invention would have been incomplete; and the century which witnessed their birth will render a glorious and worthy homage on equal terms to the two men to whom science is indebted for one of the most beautiful and fruitful discoveries of modern times. K. VERSNAEYEN.

PHOTOGRAPHY IN SWITZERLAND.

BY ADOLPHE OTT.

In the land of William Tell, photography is yet entirely in the hands of the profession; and although our alpine world would afford splendid occasions to the tourist, to take views of regions hitherto unknown to the public, I am not acquainted with a single native amateur photographer of whom you have so many distinguished representatives in your island. Why this is so, I am not perfectly able to answer. Some will tell you that we are too practical a people; but I believe that the reason for the fact in question is about the same as that which causes people in the tropics not to lay out gardens; that is, we see no need to get pictures of the scenery that surrounds us, or which we can reach and admire in a few hours.

Still, we have an excellent stock of professional men; and if you will allow me, Mr. Editor, I shall take a short review of the art in my home, and give you an idea of what we are doing.

I begin with Mr. Ganz, in Zurich, a gentleman who is, perhaps, not quite unknown to many of your readers, for he is the same who obtained medals at the London International Exhibition of 1873, and of the Exhibition of the Edinburgh Photographic Society of 1877. Mr. Ganz has devoted himself especially to the making of transparencies for the magic lantern, so much in vogue in your country; and I must say that his collection, which he is constantly increasing, is at present not only one of the most instructive, but also one of the most complete existing. The series thus far arranged include anatomy (human and comparative anatomy, histology, embryology, &c.), zoology (types of the animal kingdom), botany

(including pharmaceutical plants—useful, injurious, and suspicious fungi), forestry, geology (including prehistoric animals), physics, natural phenomena, meteorology, and astronomy. These series have been to a great part executed after drawings prepared especially by the university professors of this city. They are all carbon prints, and mostly coloured.

In connection with the art of projecting, it may not be without interest to you to know that there exists a very fine treatise in German, by Emil Stöhrer, entitled *Die Projection Physikalischer Experimente und Naturwissenschaftlicher Photogramme*, Leipzig, 1876, which gives a detailed and illustrated description for producing experiments in the domain of physics or natural history by means of the magic lantern.

Next, I have to call attention to the photographs of Messrs. Jean Gut and Co., also of this city, who are just preparing the first collection of subjects belonging to the past art industry of this country. It exceeds mostly in forged iron-work, such as gates, balconies (in lattice work), balustrades, and door-garishments. These objects date from the sixteenth, seventeenth, and eighteenth centuries; but this art has now disappeared. The collection includes also wood-carvings, statuary, and architectural work, and it is intended to make it as complete as possible. It is a pity that we have no central art museum for the instruction of the artisan.

Photo-zincography is practised by a firm in Zurich, and colotype printing by another in Winterthur.

Near the city, on the borders of the lake, we find the establishment of Dr. Richard, who formerly has given great attention to carbon printing, and has even gone so far as to introduce steam in this process, which he executed on a large scale, like Brann in Dornach. At present he does, however, little in this direction. The only carbon workers in Switzerland, besides him, are the brothers Tschler in St. Gall, and Mr. Tschler-Siguer in Basle. These gentlemen are very fine portraitists, and, in my opinion, outdo everybody else in Switzerland.

In Geneva we meet the excellent landscape workers Messrs. Charnaux and Jarcin, well known for their excellent views of the valley of Chamounix. The latter tried to introduce the Woodbury process for landscapes, but has given it up, because, as he says, Woodburytype will never give the clearness of the sky and water and the perspective, such as the silver process will yield, and I think he is not quite so much in the wrong. Besides these, almost every photographer in the mountains takes now views of landscapes, but I do not know of any one excelling. Dry plates and gelatine emulsion are almost unknown, only a photographer of this city has lately given attention to gelatine emulsion, and, as I hear, with decided success. He used English plates.

With regard to portrait work in general, I think that Messrs. Tschler can compete with the best artists on the Contieut, and Mr. Ganz makes use of the Vander Weyde process with success. The majority produce satisfactory work; still, everybody feels the "hard times," and but few have courage enough to try something new. If some of your English brethren should come to our little country this summer, I would recommend them to direct themselves to the canton of Grisons (Graubunden), which is yet the least done up. Generally speaking, the views of Mr. England and Mr. Frith are much in demand. The prices of living are now very moderate, 10 frs. being the utmost one gives for full board in the best hotel, and during the season. We invite you all cordially to come.

Höttingen, near Zurich.

WANTED TO HAVE HER PICTURE TAKEN.

[The following bit of mingled humour and pathos, from an American contemporary, furnishes some pleasant suggestions as to the amount of domestic happiness photography has contributed to.]

They had come to town to sell a waggon load of potatoes and buy a stove for the front room. After finding a market for the vegetables they were driving along in their rattled-down, crazy-going waggon, looking for a stove sign, when the old woman spoke up timidly :

"Mrs. Craigler was telling me there was a place down here somewhere where I could get four pictures for twenty cents."

The grum and grim old granger gee'd the team to get out of the way of an approaching street-car, and turning half way round in his seat on the board across the waggon-box looked the old lady squarely in the face, and with a jerking motion of the jaws, demanded :

"Picters o' what?"

"Why, of anybody—of me," responded the frightened female, with a faint little voice that would never do for city life.

"Whew! Woman, are you going clear, dead gone crazy? In the name of grasshoppers an' garter snakes what be you thinkin' of, anyway? Put that old, dried up, molasses-coloured face of your'n in a picter? Git out! Do you want to scare people to death, or bring disgrace on the pictertaking business? And do you suppose that any man with the least bit o' shop pride about him would ever let a picter o' your'n go outen his shebaug with his own name outo it? Nary time. By all the stumps in Wilkin's lot! woman, what do you want with picters anyway, at your time of life? Wasting money, too, when we need so many things a precious site was than we do nonsense like that."

The old lady coloured up and looked as though she had committed some mortal offence, as she said with much hesitation :

"I didn't mean to have you waste money on me, father, but I never had a picter took in all my life, for when I was young and would a' looked better in a frame, maybe, nobody knowed anything about such things then, an' allus afterwards the prices has been so much that I didn't think it worth while; but now since they've got 'em down to five cents apiece, I think maybe we could afford it, and I kinder thought I would like to give each of the children one for Christmas, for although I know I am not handsome, still I am mother, and when I am gone, father, don't you think it might be a little comfort to 'em to tell a little how I looked, and show their little ones; an' father, I did so hope that you wouldn't think it was foolish, and would go with me an' have our two selves took together, for it wouldn't cost any more, an' I know you would make a noble picter, father, an' I could look at it when you are away, an' it would be such a comfort to me, an' I wouldn't feel so lonesome. Do, father, please, humour me just this once, and I will try an' skrimp a little, an' save enough to make it up in a little while. Something tells me we may never have another chance, an' I would hate to have the time to come when you would be sorry—like we've been ever since poor Jimmy was took from us. You know, father, you've allus said you would give any money if you only had a picter of him as he looked before he took sick, the last time he came to town with you. Won't you, father, please?"

No longer was the farmer harsh and gruff. His eyes were moist with emotion her timid words had stirred within him, and a big tear gathered on his rough cheek and rolled slowly downward. Impulsively his arm reached out and clasped the waist of his plain old wife and gave it the biggest surprise in the shape of a squeeze known for many a day, though it was broad daylight, and hundreds of people were passing by.

"You're a trump, old woman, you are!" he cried with a loving softness in his tone. "And you shall have all the picters you want, and none o' your five cent thiugnum-a-jiggers, either, but the very best they've got in the shop. Why, you will look twenty times better'n anything I ever saw on a show bill, and a gold frame wouldn't be an atom too good for you, but it's took me a good while to find it out."

Correspondence.

RAPID DRY PLATES FOR THE STUDIO.

DEAR SIR.—I, amongst very many others, read with pleasure of Mr. W. H. Nelson's accomplishing the very thing we all want, viz., to prepare our own gelatino-bromide emulsion, and also plates, with ease and certainty, and if Mr. W. H. Nelson would kindly publish his formulæ, or let us know where the gelatino-bromide emulsion can be obtained, he will be conferring on the body of photographers a very great boon at this time of perplexity between wet and dry. I must beg pardon for taking so great a liberty, but am sure, from the tenor of his letter, that Mr. W. H. Nelson will forgive me.—

Yours, &c.,

P. H. DAVIES.

March, Cambridge.

SIR,—I read in your impression of last week "A word of encouragement to all photographers who contemplate working the rapid gelatino-bromide dry process in the studio," and was much pleased to hear that the preparing of the plates was so simple and inexpensive. I should, as I feel sure a great many more of your readers also would, feel greatly obliged if that information, making the process so simple and reliable, could be communicated through your pages. Would, therefore, Mr. W. H. Nelson kindly give the readers of the News the benefit of his experience?

I have myself worked with the commercial dry plates for a few months, but have found them to vary in result, and to fail altogether too often.—Yours truly,

D. SMITH.

Sowerby Bridge, Yorks.

DEAR SIR,—The number of communications I have had from all parts of the Kingdom relative to the preparation and use of rapid dry plates for studio work show that professional photographers are beginning to take a deep interest in the matter; but as time will not permit my replying individually to all, will you kindly favour me with a corner to answer a few questions, and set some doubts at rest.

I am asked, "Are dry plates certain?" "Are they really practical for studio work?" "Are the results uniform?" "Do the plates keep?" "Are they not very slow in printing?" &c., &c.

Well, I can safely say they are absolutely certain, and thoroughly practical for studio work, much more so indeed, than collodion; their uniformity is far before collodion, as they are free from the constant change that is taking place in the relations of collodion and bath. Today's dry plates are the same as yesterday's, and to-morrow's are the same as to-day's, and so on, always ready, always the same; no oyster-shell markings in warm weather, no comets, no pinholes, no fog; they keep well, but must be kept in a dry place, and free from deleterious vapours. Carefully kept, I have every reason to believe they are unalterable for years.

As to printing quality, all degrees of density are obtainable with gelatine, from the thinnest and most delicate negative, printing as quickly but more brilliantly than collodion plates of a similar class, to as dense and strong a negative as any one need ever wish for, these results being under the most complete control.

The development, so far from being troublesome, as some appear to think, is just the reverse, the negative being ready for fixing in twenty to thirty seconds after applying developer, intensification being very seldom necessary, and even then not more than ten seconds' work.

With regard to fixing, I may here mention, for the benefit of those beginning to use gelatine plates, that after removal from the hypo they should be fully washed without any delay, as the colour of the film is very much and very quickly injured by being left wet with any trace of hypo in it; to allow plates to dry in that state is of course

utter ruin. I must say that I never worked with such pleasure at my business as I have done since adopting gelatine dry plates, and I believe this will be the experience of every one else.

To meet the wishes of many correspondents, I may add that I have arranged to give practical instructions in gelatine work, as will be seen on reference to the advertising columns.—I remain, dear sir, yours, &c.,
Twickenham, S.W. W. H. NELSON.

Notes and Queries.

THE PERPLEXING BATH.

SIR,—A letter signed "Puzzled," which appeared in your last impression, reminds me of similar experience. The cause I traced to a bad sample of filtering paper. It may not be generally known that some samples of paper are quite unsuited for filtering silver solutions, and that the fibre of some paper contains wool, and is partly soluble in baths. I would recommend your correspondent to add a few grains of nitrate of baryta to his bath (say about two grains to each ounce of solution), and carefully filter through *French filtering paper* (that sold in packets and cut circular). He will also do well by using common alum in addition to the sulphate of iron, &c., in the developer, in about the same proportion as the iron.

I believe that if the above suggestions are strictly adhered to, your correspondent will be no longer puzzled.—I remain, yours,
ERUCA.

Proceedings of Societies.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Society was held at the usual place of meeting, Museum, Queen's Road, on Wednesday, May 7th, Mr. WEBBER in the chair.

The minutes having been confirmed,

The Hon. SECRETARY produced a letter received from the Vienna Photographic Association.

Mr. Wood, of Bath, was unanimously elected an ordinary member.

The CHAIRMAN then called on Mr. Robert Biggs to read his paper entitled "A few Practical Illustrations of the Value of Photography in Law and Medicine" (see page 320).

The CHAIRMAN spoke of the great truth of Mr. Biggs' remark that drawing was utterly inadequate to represent the many most useful objects of scientific and medical interest and legal evidence which photography so effectually and conclusively did.

Mr. BIGGS said that as a medical man he had simply to place a photograph of any peculiar case at the top of his note-case book, and place his notes beneath, and the case spoke for itself with a clearness equalled by no amount of elaborate explanation.

Mr. POWELL asked if it would not be evident in the case of the altered book that the thinness of the part erased was conclusive.

Mr. BIGGS said it was even on such points perfectly clear, and that no photographic jury would, for a moment, have thought of acquitting the accused.

Mr. H. A. II. DANIEL brought before the Chairman the photographic evidence at the Tichborne Trial, and said he could never understand why it was so easily passed over, being from a medical point of view so important.

Mr. BIGGS said that fortunately juries were not all skilled, for if such delicate evidence were made so very important, the public would express much dissatisfaction through not understanding it; but in the case adduced by Mr. Daniel, if a medical man had been told that the ear represented in the photograph and that of the Claimant were the same, he might listen, but certainly would not believe it. He stated that the success he had had with gelatine plates would enable him to photograph many subjects of peculiar forms of idiocy now under his care, and as the new post mortem room at the hospital was under his direction, having been fitted up so as to be easily altered for photographic purposes, he hoped soon to be able to exhibit some peculiarly interesting specimens.

On the motion of the Chairman, seconded by Mr. Daniel, a

cordial vote of thanks to Mr. Biggs for his paper closed the meeting.

The paper was listened to with intense interest, the subject being one which placed the art in a very new light before the members.

It was decided that the first excursion meeting should take place on Wednesday, 28th inst.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

AT the meeting of February 4th, with President NEWTON in the chair, after the reading of the minutes and acknowledgment of receipt of various photographic publications,

The PRESIDENT introduced to the Section Mr. J. Traill Taylor, from London, stating that he had come to live in New York, and make it his home.

Mr. TAYLOR, in returning thanks, stated that it was not only his intention to live there, but to apply for a membership of this Section.

Dr. VANDERWEYDE exhibited to the Section some pictures taken by his son in London by the electric light.

Mr. DUCHOCNOIS said that he had received some from Paris from M. Liebert, who had bought the Vanderweyde process.

Dr. VANDERWEYDE said that the difficulty in taking pictures by artificial light was that the shadows were very black and the lights exceedingly strong, owing to the fact that the rays of light were divergent, coming from a point, whereas daylight was convergent. To overcome this difficulty his son used a combination of a parabolic reflector with a Fresnell lens. The light was placed in the focus of the reflector, which was of white enamel, to imitate a white cloud; the rays of light were reflected upon the lens in parallel rays; passing through the lens the rays converged on the sitter, who was placed a little within the focus of the lens. The sitter was entirely screened from the unpleasant glare of the light. The time of exposure was ten to twenty seconds. He used carbou points. The exposure was so short that he had no trouble about the steadiness of the light.

Mr. TAYLOR said that if he had been aware that this subject would have been brought up, he would have brought some specimens. He had been photographed by the electric light, and certainly there was at least one side reflector used to illuminate the shadows on that occasion. A simple apparatus, being used very extensively now, and wonderfully cheap, was composed of somewhat rude parabolic reflector, in the centre of which was a small lantern (although not necessarily in the focus) with violet coloured glass. This was all covered over with a piece of paper, which acted as a white cloud; a small quantity of some pyrotechnic compound rich in actinic light-producing properties was ignited, and in the space of ten, fifteen, and, in some cases, twenty seconds, a very admirable picture might be taken.

Mr. CHAPMAN did not see how the deep, heavy shadows could have been got rid of without the use of additional reflectors. Still, if he had reflectors to light up the shadows, it was what all needed, even under a skylight.

The PRESIDENT had made a negative by request with a view-lens made for out-door work, for taking groups mainly, about fourteen inches focus. It was made on an emulsion film, but mainly to see whether the emulsion was sensitive enough to work with a view lens in-doors to make a portrait of this size, about a four-inch head. It was not a very perfect negative, but it demonstrated the fact that the emulsion was sensitive enough to work with that kind of a view-lens. This plate was exposed one minute. With the ordinary bath process it would have required from four to six minutes' exposure. He would say, in reference to the time, one minute under his light; at this time of the year it took at least four times the exposure required when the sun was higher, say from May to September. He would take that same picture in twenty-five seconds, perhaps twenty, with as much effect of light as there was on the negative shown.

Mr. TAYLOR said he looked upon the production of such a picture in the time given as an immense advance.

The meeting then adjourned.

AT the meeting of March 4th, after transaction of the usual routine business, the SECRETARY read a communication announcing the appointment as a Committee on Chemistry and Optics for 1879, of Messrs. T. D'Oremieulx, Charles Rice, D. C. Chapman, the gentlemen nominated by the Committee appointed for that purpose at a former meeting.

Mr. DUCHOCNOIS, on behalf of the committee appointed to nominate officers of the Section for the ensuing year, reported as

follows: Mr. H. J. Newton for President, Mr. J. B. Gardner for Vice-president, Mr. D. C. Chapman for second Vice-president, and Mr. O. G. Mason for Secretary.

Mr. MASON exhibited to the Section a small evaporating dish made of sheet iron coated with a glaze which was proof against acids or alkalis. It had been tried at the Bellevue Hospital, and found to be very good, and would be used there instead of those heretofore employed. They would stand fire, and were not liable to break. He also exhibited some photographs of subjects taken at his studio in Bellevue Hospital. In his remarks he said: I do not exhibit these prints as specimens of fine photographic work, but as curiosities of disease, and how photography is used to illustrate diseases. Some of them show the patient both before and after treatment. Such subjects are not very easy to keep still a long time, because most of them are in pain. Something more than ten years ago I was requested by several members of the surgical staff to illustrate the diseases treated at the hospital, and after considering the matter some months, finally accepted the proposition and was appointed the official photographer for the department. There were at that time only three surgeons on the staff who seemed to have an idea that photography could be made useful, or, rather, that it might prove an important adjunct to their work. These three had their most important cases photographed when they were received, and after an operation, or when they were discharged. After two or three years other members of the staff, seeing the importance of the work, slowly came in for their share, until, at the present day, the men who first took little or no interest in the introduction of photography patronize it the most extensively. I made for some of these surgeons a large number of prints of important cases, of which some are sent to Europe to illustrate the processes used in the treatment of diseases in New York. I make three copies which I furnish free, one to the visiting surgeon in attendance, another to the house surgeon who has charge of the case, and another print I mount in the book of the hospital. Other prints are made on the surgeons' private orders at little more than cost price. When you refer to the hospital books provided for the last few years, you can find the most important surgical cases not only fully described, but illustrated. Many observers have thus been able to avoid mistakes and errors which have been brought to their notice through the means of photography. Thus we see that the surgeons and the histologists, like most other scientific men, are more or less dependent on photography in recording for others what they are doing.

Mr. CHAPMAN: In cases of this kind, and in a great many other cases, photography, they say, don't lie; in fact, it does not lie, but it fails to tell the truth. The colours, of course, are wanting. You have the form, but no colour. If that could be added, the results, of course, would be perfect. But as far as the colour is concerned, or the relative lights and shadows, there is a good deal that it does not tell the truth about.

Mr. NEWBERRY exhibited to the Section some photographs said to be in permanent colours executed by his daughter. One of the pictures was made fourteen years since, and another seven or eight years. Neither appeared to have faded in the least.

Messrs. Mason, Attwood, and Chapman having been appointed a committee for the promotion of a stereopticon exhibition of work at the next meeting, the Section adjourned.

Talk in the Studio.

TELEGRAPHIC PHOTOGRAPHS.—An ingenious apparatus, intended to reproduce telegraphically at a distance the pictures obtained in a camera-obscura, has, says *Galvani*, recently been invented by M. Senlecq, of Ardes. The principle on which it is based is the property possessed by selenium of presenting a very variable and very sensitive electrical resistance according to the different gradations of light.

PHOTOGRAPHY BY ELECTRIC LIGHT.—An American contemporary says: "It has become quite the fashion in Paris for parties of ladies and gentlemen after dinner, or on their way to the opera, to step into a studio and have their photographs taken by the electric light. It is, moreover, said that the Americans are the best patrons of these night studios."

CEMENT FOR UNITING METAL TO GLASS.—The following recipe is from the *Monthly Magazine of Pharmacy*: Take 1 pound shellac dissolved in a pint of strong methylated spirit, to which

is to be added 0.05 part of solution of india-rubber in carbon bisulphide; or take 2 ounces of a thick solution of glue, and mix with 1 ounce of linseed oil varnish, or 3-4ths of an ounce of Venice turpentine; boil together, and agitate. The pieces cemented should be fastened for fifty or sixty hours to get fixed.

To Correspondents.

W. W.—The address of Mr. England is 7, St. James's Square, Notting Hill, W.

B. Cross.—There are various methods by which the plate can be kept from touching the bottom of the bath. If a glass dipper be used, let the ledge, or shoulder on which the plate rests, be cemented on the long strip of glass about an inch from the bottom. If the dipper be made of silver wire, it can have projecting feet to prevent the plate going to the bottom; or a hook, or ledge, can be cemented to the back, by which the dipper may rest or hang upon the back of the bath, at any depth which may be chosen. The kind of dipper used will chiefly influence the plan chosen, but there are many methods of carrying out the same idea. It is a wise thing to attend to. We have often seen one end of a negative covered with spots from the sediment at the bottom of the bath being stirred up, and falling on the lower end of the plate.

G. Young.—Opinion and practice are much divided. As a rule, if a photographer have an extended connection for large work, he will produce large negatives direct for all sizes up to sixteen inches by twelve inches; if he have only occasional work to do, and have not appliances for doing large work direct, he will take a small negative and enlarge. Skilful men will produce good results by either method. If by enlargement, the best plan is to produce an enlarged negative from a transparency. For large direct portraits, a portrait lens of long focus answers best.

News.—The name and address of the Secretary of the Manchester Photographic Society are as follow: Mr. W. J. Chadwick, Prince's Bridge, Manchester. 2. The term doublet is applied to a double combination, such as a portrait lens. The lens to which you probably refer is the Symmetrical Doublet of the firm in question. It is used for various purposes, such as groups, architecture, landscapes, &c. The Ross' Catalogue you have, which makes no mention of the lens, is probably an old one. The lens has been introduced a few years.

NOVICE.—You may calcine oyster shells by placing them on an iron shovel and submitting them to a strong heat until they lose their shape and fall into powder. But if you wish to experiment with phosphorescent photographs, you had better purchase your sulphide of calcium of a manufacturing chemist.

THOMAS LIONS.—You do not state what kind of colouring the preliminary preparation is intended for—water, oil, or crayons. For oil colouring, a size made by dissolving isinglass in weak alcohol and water, by gentle heat, answers very well. We cannot give you proportions, as we have always judged by the eye in preparing it, and have not seen a formula. For water colour, a very dilute sizing of the same preparation answers well. Or, take an ounce of spirit varnish, and add to it two ounces of water in which twelve grains of borax have been dissolved. Newman sells an excellent preparation for the purpose.

R. M. F.—Kaolin is used—or, rather, used to be used—for removing the brown discolouration which the printing bath at times acquires from contact with albumenized paper. Agitating the solution with kaolin, and filtering, removes the colour; but the use of kaolin has been largely superseded by the simpler plan now employed.

K. B. Y.—The deep purple colour in your toning bath indicates precipitation of the gold. It will certainly not tone satisfactorily when the gold is precipitated. You had better make a new one at once. The misty, indefinite effect is much increased by the want of definition. It may arise from want of careful focussing, or from general unsteadiness of the sitter, or from the use of an imperfect lens, or from want of firm contact between the paper and negative in printing.

A. M.—If you form a canopy of calico to project about five feet from the top of the wall, and place your sitter under it, the wall forming the background, the sitter being placed about two feet from it, you will probably find the effect very good. If you manage the position right, you will not, we think, require screens or reflectors at the side.

AMATEUR.—A lens of the group class, or a portrait lens moderately stopped down, will answer.

ROGER LAURENT.—You shall have one of the prints in question. Several Correspondents in our next.

The Photographic News, May 23, 1879.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE CAMERA IN LAW AND MEDICINE.

THE paper recently read before the Bristol and West of England Amateur Photographic Association, by Mr. Robert Biggs, M.R.C.P., the Deputy-Coroner for Somerset, proves once more how useful photography can be in law and medicine. It is some years ago since the late Dr. Wright pointed out, in a communication to the Photographic Society, the various educational purposes to which photography might be applied in connection with medical students, and other physicians, in Paris and elsewhere, have, from time to time, demonstrated how important the camera can be in almost every branch of medicine. In forming a diagnosis, or in scientific investigation, a knowledge of photography has many times proved exceedingly useful. We remember but two years ago seeing at the Paris Exhibition of photography some striking examples of camera work in connection with medicine. An apparatus termed the pulsograph was exhibited by Dr. Ozanam, whose name as a medico-photographer is already well known. He it was, if we remember rightly, who was the first to point out—or, at any rate, to prove beyond doubt—that not only was there a double action in the beat of a pulse, but a treble and quadruple movement at times. His *modus operandi* was to place upon the wrist or heart of the patient a bag or reservoir of mercury, which was in connection with a tube something like a barometer. The beating of the patient's heart influenced the mercury in the tube, which rose and fell according to the nature of the throb. By placing a light in front of the head of the column of mercury, and a sensitive film at the back, which sensitive film was capable of moving along gradually in a horizontal direction, a wave-line was produced by way of a photographic image. This wave-line corresponded to a rise and fall of the mercury column; and if there had been a flowing wave-line produced, we should have known the action of the heart was uniform and regular. But Dr. Ozanam proved by his pictures that the action was not regular, but that on occasion the mercury column, though rising at one leap, descended again in two or three. The state of the heart could thus be ascertained in a very simple manner of any patient. Moreover, an investigation of the pulses of human beings of various ages, in this way, has also brought to light important points. Dr. Luys, a French surgeon, recently exhibited a whole series of these pulse photographs. Thus, a picture representing the pulse of a boy beating 80 to the minute showed scarcely a wave-line at all, but a succession of sharp zig-zags. A man in the prime of life, whose pulse beats 55 to the minute, gives a picture of a less number of waves; but they are higher and more vigorous than those furnished by the boy. When we come to examine the pulse of a centenarian, which Dr. Luys succeeded in photographing, the feeble action of the heart produces but a series of low-rising curves. A large number of photographs of the brain and skin in health and disease were also exhibited, we remember, in Paris two years ago, to exemplify the use which French medical men now make of the camera in the way of teaching and recording. Mr. Biggs, in his interesting paper at Bristol, the other day, touched upon another and no less important matter, the assistance a photograph may lend the coroner and jury in making up their minds to an issue. Several instances were mentioned in which the camera had done good service in this way. In one case a child of three or four years of age was found dead, about which the post mortem examination left little room for doubt: the child had been starved to death, its form was terribly emaciated, and appeared to have been carried to an out-of-the-way spot to be got rid of. There was no one in the neighbourhood who could have been the

parent of the child, but a photograph was taken of the remains, and the picture given over to the police at the nearest cities, Bristol and Bath. The result was that within three or four weeks of the inquest the photograph was recognized by neighbours, and a woman found, who was convicted of murder. Going to another case, which came under the Deputy-Coroner's attention, we find an equally important application of photography bringing the truth to light. There had been a serious railway accident, and the principal point turned upon an entry in the signalman's book. An examination of the book was made, and the appearance of the entry led the Coroner to suspect it had been tampered with. He himself, however, could not express an opinion one way or the other, and the jury were divided in their judgment. On his own responsibility, Mr. Biggs had a photograph taken of the page and suspicious handwriting, and the photograph was afterwards enlarged, when the result was to prove unmistakably that there had been erasure and modification of the original figures. We remember a parallel case to this that was tried in one of the Paris courts a little while back. It was a question of a disputed will. A will was produced which was not only suspected to be a forgery, but the person who had accomplished the misdeed was suspected too. To prove the case, some words in the suspected will were photographed and enlarged, together with a few words avowedly in the handwriting of the accused, and enlargements of the two photographs turned out sufficient for conviction. There was a tiny spluttering noticeable in the upstrokes, where the pen was arrested, and this characteristic spluttering was common to both writings. M. Gobert, the photographer attached to the Bank of France, as our readers know very well, has been fortunate to discover many erasures and modifications on cheques and bills by the aid of photography, and that establishment finds it worth while to have a photographic studio fitted up on the premises, so indispensable has the camera become as a detector of wrong-doing. Again, to secure truthful records of the results of operations in surgery, the camera, Mr. Biggs points out, is invaluable. A photograph of a person with a squint, before and after an operation, shows how successful the latter has been. If drawings had been substituted in such a case, they would have been of little or no value. No one would have known how much or how little they had been exaggerated—how much or how little the deformity, or cure, had to do with the photographic result; but knowing, as Mr. Biggs says, the veracity of our witness, we may rely upon the photograph as truly as upon our own eyes. Again, says Mr. Biggs, some time ago an American surgeon devised a new mode of treatment in a disease known as spinal curvature. He published the details of his treatment and description of his apparatus; but to make his description more clear, illustrated his works by photographs, showing the steps of his manipulation in its various stages, and rendering the whole so clear that any medical man could see and understand the plan without further knowledge. The College of Surgeons in London possess at this moment a very valuable series of photographs representing subjects of interest to the medical profession, all of which are far more useful than the most skilfully executed drawings could possibly be. In our medical schools, too, photography now holds an important place, and diagrams enlarged by the camera are put before the student in lieu of the free-hand productions formerly employed, while in some cases the pictures exhibited are obtained by throwing upon a screen enlargements of photographs by the aid of a magic lantern or similar contrivance. In this way the microscope is to some extent superseded—and the microscope, as everybody knows, is very difficult of employment in the class-room. It would be interesting if other of Mr. Biggs' brethren would come forward to add to the valuable experiences which that gentleman has recently given us of the assistance that a Coroner derives from photography.

FRENCH CORRESPONDENCE.

PHOTOGRAPHY AT THE INDUSTRIAL EXHIBITION OF MARSEILLES—POSITION OF PHOTOGRAPHY AT INDUSTRIAL EXHIBITIONS—CARBON PRINTING AT MARSEILLES.

Photography at the Industrial Exhibition of Marseilles.—Since my last letter nothing new in the region of photographic discovery and progress of which I can give an account has occurred among us; moreover, I have been on a trip of some days to Marseilles, and have taken advantage of my stay in that important city to make myself acquainted with the photographic work that is being carried on in it. At the time of my arrival an industrial exhibition had just been opened, with a competition for prizes open to manufacturers of the district only. I had hoped to find also an adequately represented photographic section in this exhibition, as the district to which the competition is limited comprises seven or eight Departments of the south of France. To my great astonishment there are only three or four exhibitors of photography, notwithstanding that there are at Nice, at Montpellier, at Nîmes, without including Marseilles itself, photographers of great repute. It is difficult to explain this remissness, unless it be owing to bad management on the part of the executive of the exhibition, or to a general disinclination to take part in these shows, which are now becoming quite wearisome from their frequency. The photographers of Marseilles had, however, originally consented to exhibit on the condition that their works should be placed in the same gallery as that in which the Fine Art Section of the Exhibition was installed. They were unwilling to have their works mixed up with those included under the head of manufacturing industry proper, and they urged that if photography be not itself a fine art, it is at any rate entitled to be ranked as an important ally and auxiliary of the fine arts; its place is, therefore, by right in immediate contiguity with the latter, and nowhere else. This perfectly well-founded claim was at first admitted; but the authorities having subsequently changed their mind, the photographic section was relegated to the department where are shown pomatum pots, forcing pumps, and garden engines. Of course, this highly incensed the photographers, and they nearly all declined to exhibit. Thus our art has missed an excellent opportunity of advertising itself; but, then, "principles above everything"! At Marseilles an attempt was made to raise the banner of photography so high as to place the art in a position of its own. Without claiming for it the same rank as the creative arts occupy, the promoters of the movement were satisfied that it had the right to be considered the indispensable auxiliary of those arts, and that in this character it should be allowed to march at their side.

Position of Photography at Industrial Exhibitions.—This question has become one of considerable importance, and it is true that a precedent was established which could be brought forward on future occasions of the same kind. At Paris, the exhibition of the Photographic Society of France is generally held at the *Palais de l'Industrie*, in an annexe of the Fine Art Exhibition—the *Salon*. But at the International Exhibition, photography was classified with the manufacturing industries; and, in reality, if we institute a comparison between the scientific and the artistic aspect of photography, its place would seem rather to lie among the industries. I have nothing to say, and am well pleased if, considered as one of the arts of reproduction, it may be included among the retinue of the fine arts; at the same time I do not think that there is any occasion to sulk and feel sore because it is relegated to the company of the manufactures. I do not imagine that a photographer, however much he may be an artist, will so far overcome his artistic instincts as to assert that the results he produces are works of art; they may satisfy artistic conditions, just as is the case with a suite of

carved furniture or a piece of fine tapestry, or an exquisite porcelain vase. But all these objects are classed among the produce of manufacturing industry, or among the decorative, but not among the fine arts; they are the result of a mechanical or scientific application to art. The human hand has had no further part in the production beyond directing the tool or the machine employed in the manufacture. It is from this standpoint that a distinction is established—and rightly, in my opinion—between works of art properly so called, and those in the production of which art is certainly made available, but only in the character of an industrial application. The true place of photography is, on this showing, rather in the category of the industrial, than in that of the fine arts; the latter must be limited to the arts of drawing, painting, and sculpture, or in addition of original lithography and engraving. It is not the first time that this subject has given rise to differences of opinion, and it seems to me to be quite time to get some decision accepted by the majority of those interested, a decision which should put an end to any future difficulties of the same kind.

Carbon Printing at Marseilles.—However that may be, the photographic section of the exhibition at Marseilles cuts but a sorry figure, and it struck me I should employ my time to greater advantage by paying a visit to the principal photographers of the city, and studying the work that they execute. It gave me real pleasure to observe that the two well-known houses of Chéri-Rousseau and Cayol Brothers are working the carbon process on a large scale; they use it for producing prints with a light tint of colour. It is true I am not an admirer of these prints, in which the colour is scarcely indicated; but, like everything in the way of novelty, it is a question of the fashion of the hour. The process in this form, however, is very easy of manipulation, for it is only necessary to spread a light coat of colour over the face of the carbon prints previous to their final transfer. Messrs. Cayol transfer their carbon pictures, coloured at the back, to the same kind of paper as is used for producing drawings in two crayons; the effect to anyone who does not know how it has been produced is—one can scarcely say artistic, but, perhaps, pseudo-artistic. It certainly conduces to making the tone less dry than that of a simple photograph in monochrome, and in this respect I believe that the firm are in the right road to produce some charming results. M. Chéri-Rousseau has a large establishment at St. Etienne—one better known than this at Marseilles, which he has only recently taken over. Here he produces a particular kind of pale photograph by the photochromic process; his pictures give one too much the impression of the black or grey of photography, and if he wishes to make use of the process of photochromie, I should like to see him do so more thoroughly. All the enlargements produced by this firm, as well as that of Cayol, are executed by the carbon process—an example which should be followed by all photographers. Though the carbon process has not yet been practically applied to taking small photographs of the *carte-de-visite* or album size, it cannot be said with truth that it has not been employed on a complete scale for the production of large pictures. It must be looked for that the public will become more exacting, and will want to have permanent photographs of every size, though at present they are scarcely aware what the term implies. I happened to be present in M. Cayol's shop when a customer, a man in society, came in to inquire the price of an enlargement. On being told by the proprietor that he would get a *carbon print*, he replied: "I don't know what that means, but I feel sure you will treat me quite fairly." In short, the public must be educated before we can expect to become more general the employment of the processes by which permanent photographs are produced. But it will come!

LEON VIDAL.

TICHBORNE—AN EXPLOIT FOR SCIENTIFIC PHOTOGRAPHERS.

BY WILLIAM MATHEWS.

"Not only does photography reproduce with absolute perfection details which the most scrupulous eye-work could not trace without error, but it actually sees what is invisible; the sensitive plate receives impressions which altogether escape the human eye."

Mr. H. Vogel, of Berlin, cites the case of a lady who had always, as the phrase is, 'taken well.' She 'came out' one day all over little black spots. Two days after, it became evident that the lady had the small-pox. In fact, she died of it soon after. Her face must have been covered with very faint yellow spots before any eye could trace the least mark upon the skin."—*All the Year Round*.

IN various of the scientific journals the above passage has been quoted from *All the Year Round*, pointing out the remarkable faculty inherent in photography of bringing to light details that under other circumstances are invisible, or that have altogether escaped previous detection.

In view of the substantial accuracy of this statement, the inventor of the appliance known as the "Identiscope" deems himself called upon to give publicity to a fact that for some time has been within his knowledge, and which he sees no good reason any longer to refrain from divulging. The manifest disinclination of a trusty friend or two of the Tichborne Claimant, in regard to venturing upon what they have deemed to be dangerous ground, has been the chief influence during the past twelve months in restraining the writer from submitting the matter at issue to the public cognizance of authorities in the photographic art.

The series of life-size photographs of the "undoubted Tichborne," and also of the "Tichborne Claimant," now in the possession of the writer, were produced, he believes, from negatives derived directly from the sworn portraits used in the trial at Bar. They were supplied by Messrs. Maull and Co., of Piccadilly, and their perfect authenticity is beyond all question. The "original," it is superfluous to say, remain under the seal of the High Court of Judicature.

The several "copies" above spoken of were subjected by the writer to that special geometrical admeasurement and linear sub-division which is an essential attribute of the Identiscope. The scrutinizing introspection of details which the process involved, and which in effect extended over some months, resulted, ultimately, in the assured conviction on the writer's part that evidence of a remarkable and most conclusive nature had an unsuspected existence upon the portraits of both epochs.

In a word, the Daguerreotypes of the undoubted Roger Tichborne, taken at Santiago, January 1854, and the photographs of the Tichborne Claimant, taken at various times, bear alike and undoubtedly extensive vestiges of an ornate device, which (evidently at an early period of life) had been inwrought by puncture upon the fabric of the skin.

If this fact be one capable of verification, it is of no secondary nor immaterial nature. At the same time, when the writer remembers that some months had elapsed before he himself was cognisant of the presence of these tracings, not to say they had escaped the notice of the artists who produced the photographs, it cannot be a subject of surprise should the announcement be received with some degree of incredulity; and, certainly, if it be only when the eye has undergone a process of education that their visibility is ensured, there will be still sceptics who will deny their existence altogether.

But the writer recurs to the passage quoted from *All the Year Round*, and relies confidently upon the advancing skill of photographers, and upon the latent powers of their art. He therefore invokes their aid. Fortunately, the copies of the Tichborne portraits have been multiplied most extensively, and are disseminated into every quarter of the globe. If, then, photo-

graphy really possess the remarkable faculty attributed to it, no fear but that the means will be devised of causing these portraits to render up the secret they have so well kept. In one aspect, it may to some be even deemed a matter of congratulation that so cogent a piece of evidence has so long remained hidden alike from friend and foe. For certainly, when it is remembered that the Tichborne Claimant has been incarcerated for years, without one thought of any such evidence—which has been neither appealed to, nor its existence in the least suspected—it negatives at once and for ever all suspicion of fraudulent origination.

Whilst commending confidently the verification of this disclosure to the attention of qualified experimenters, the writer would indicate to such the direction in which he has himself sought success. It should be known to them that in the instance of mathematically superimposing photo-transparencies of the Tichborne portraits of the two separate epochs (1854—1874), they have resulted in producing a likeness in which every feature is in perfect correspondence, and this "Tichborne Blend," originated some twelve months since by the writer, was, in point of fact, the first example of a veritable "composite portrait" that had been anywhere produced.

Similarly, he would now point out that an exact superimposition, by the same geometric method, of two of the self-same portraits, in which, singly, the tracery may be only very dimly discerned, would result in the tracery becoming more distinctly apparent—owing to its perfect duplication.

There is another mode in which a partial verification may be also obtained by those sufficiently conversant with such matters. If the selected portrait be turned toward a mirror of the highest quality, the portrait at the same time receiving the fullest possible accession of daylight, there will result a duplication of the image, (1) on the surface of the glass, and (2) on the silvering. By suitable adaptation higher results than those yet arrived at would be doubtless attainable by either method.

An important element must be borne in mind in all such experimental tests. With vestiges so faint, no additional enlargement of the image is likely to avail anything. On the contrary, the pattern (constituted, as it is, of very minute cicatrices or papillæ, barely discernible, probably, upon the living face) must be drawn together, so to speak, until the scattered particles again coalesce. The carte-de-visite dimensions, on the other hand, will be too diminutive for the desired purpose.

It is necessary to say that of the Daguerreotypes, the three-quarter portrait supplies the markings in the largest degree. This is partly owing to the manner in which the light fell upon the sitter; but in greater measure from the apparent fact that all copies in circulation of the full-face portrait have been derived from an original that had been "improved" by artistic stippling. The effect of the varied direction of the light may be observed also in the photographs of Sir Roger, the Claimant, making the tracery, in some of the sittings, much more perceptible than in others.

At this stage the writer confides, hopefully, the investigation into abler hands. But, before concluding, he would crave permission to be permitted to say thus much. In his view, the attestations which record the uniform propriety of the claimant's Australian life constitute an element entitled to recognition even here. Certainly, the common allegation, "Oh! he was a bad fellow, whoever he may be," cannot be sustained when fairly challenged. Mr. Gibbes and Mr. Cubitt both accredit him, as of a matter within their own knowledge, that in Australia he had done nothing "of which a man need be ashamed."*

* It is obvious that the question discussed by Mr. Mathews in the above article is a purely scientific one, and its interest is not in any degree affected by the moral character of the Claimant either in Australia or elsewhere.—Ed.

COLLODIO-BROMIDE EMULSION.

BY W. B. WOOD.*

HAVING been asked to read a paper on the mode of preparing my collodio-bromide emulsion and plates, I will commence without wasting any of your time, stating to whom I am indebted for various hints. Before going into details I wish to say that, from the report of last month's proceedings, I have no doubt many of you will be under the impression that I am about to give you an extra-rapid process. Such is not the case, as it is only moderately so; but it is to be depended upon, and, what is also an advantage, both emulsion and plates keep well. I have kept plates four months, and emulsion four to five months, and yet both have worked well. I generally give a little more exposure for an old plate or emulsion. By being able to work very quickly, I mean that the emulsion and plates are easy of preparation.

We will first commence with the bromised collodion. For convenience sake we will make what will be, when sensitised, two ounces and five drachms, although I recommend the bromised collodion to be made in much larger quantities, as it improves by keeping, and also enables you to take the requisite quantity perfectly clear.

Into a bottle pour of alcohol (795) two drachms (if you use it of a greater specific gravity it is liable to produce crapiness and uneven films); into this put of cadmium bromide (crystallised twenty grains, or, if you use anhydrous, sixteen grains, and ammonium bromide nine grains). When all is dissolved add pyroxyline, H. T., five grains, and of the ordinary three grains. If you prefer it you may use all high temperature, but I find it gives a film rather too powdery. When the cotton has soaked add methylated ether (720) twelve drachms, and shake well. This is your bromised collodion.

To sensitise the above, pour into a yellow, wide-necked, stoppered bottle, capable of holding four or five times the quantity (by having it with a wide neck it enables the silver to be added without running down the sides of the bottle), three-fourths of the above collodion, and place the bottle in a vessel of only lukewarm water. Into a test-tube put thirty-seven grains of powdered silver nitrate, and add to it fifteen minims of water; then apply heat until all is dissolved. Measure out seven drachms of alcohol, and pour about five and a-half drachms into the silver nitrate (gradually warming between each addition); keep back the remainder for the final rinsing of the test-tube. Apply heat again, and when all the silver is dissolved, pour gently into the collodion, a little at a time, shaking well between each addition. I generally place my test-tube in a jar of hot water while I shake the bottle; this prevents the silver falling. In about three minutes after the last of the silver has been added, pour in the remaining portion of the collodion, shake very well again, and place aside for twenty-four hours.

To test the emulsion proceed as follow:—Immerse white paper in a saturated solution of potassium bichromate, and dry in the dark; afterwards cut it up into strips for use. When the emulsion has rested the requisite time, shake well and dip in one of the test papers, and if it turn red there is an excess of silver. To correct this add more collodion, estimating the quantity as near as possible by the depth of colour. Do not judge the paper by transmitted light, as it is apt to deceive you; the coating of the emulsion adding to the thickness of the paper makes it appear red, when such is really not the case. You may, however, test it in any other way familiar to you.

To prepare your plates (which must have a substratum), shake up the emulsion well several times, and test its flowing properties; if it set in furrows, add more ether and alcohol (other two parts, alcohol one part) until it gives an even film. After the last shake, let it stand five or ten minutes; then filter through linen into another bottle a sufficient quantity to coat your plates. Place the funnel in the stock bottle and commence coating your plates, draining the excess into the

stock bottle; now rock your plates well to prevent waviness, and always carefully wipe the neck of the bottle before coating the succeeding plate. When the film is fairly set, and not before (as I have noticed that one cause of uneven densities in films is through dropping them into the wash water too soon), drop it into the wash water, and allow it to remain until greasiness has disappeared. Before taking it out rock it a little, and place it in, or flow over, the preservative for about one minute (I use plain beer perfectly flat; if it be not so, place it in a warm place for a short time). Remove the moisture from the tack of the plate and rear it on one corner in the drying-box, allowing it to rest on three or four folds of blotting-paper (I place mine in a draining-rack until all are finished, and before putting them into the drying-box I remove the pool of preservative from the bottom with a piece of blotting-paper. These plates do not require any backing, being almost as dense as a zinc bromide plate, although only containing about two-thirds the amount of cotton.

Exposure.—I give on a clear day (April), with a Ross' portable symmetrical No. 3 and stop No. 3, three and a-half to four minutes, according to subject.

Development.—Drop the plate into a dish of water and allow it to remain until greasiness has disappeared. Make up beforehand the following solutions:—

No. 1.—Pyro	96 grains
making up to 1 ounce in alcohol.	
No. 2.—Ammonia (880)	1 part
Water	8 parts
No. 3.—Potassium bromide	20 grains
Water	1 ounce

into (say) 3 drachms of water; add one or 2 drops of Nos. 1 and 2.

Stir with a glass rod and flow over the plate. If it has been properly timed it will come out gently. Do not force the picture, but wait patiently, and should you require more detail, add more ammonia; if more density, add more pyro. I always intensify my pictures, after fixing, with Mr. II. Cooper's gelatino-iron intensifier.

I cannot say how long the plates will keep after exposure, the longest period I have kept one being a fortnight, and it developed quite as well as one that had been exposed and developed the same day. I do not advise keeping plates after exposure, as you may, if necessary, develop them by the aid of a naked candle, if the latter be kept at about two or three feet from the plate.

In conclusion, allow me to advise you to test the flowing qualities of your emulsion on a small plate before coating large ones, and, if necessary, dilute it; shake well again, and allow to rest five or ten minutes before using. Never employ beer unless it be perfectly flat. You will find it wise to pour a little of the water with which you intend to wash your plates into a glass and examine it. I have sometimes found it muddy in consequence of repairs in the streets. Never filter your emulsion into a bottle with old emulsion sticking to the bottom. The best way to remove it is to place a quantity of small glass beads with water into the bottle and shake well; this will remove the film when acids, &c., fail. And, finally, let me say that should the process be thought worthy of your consideration, I shall feel amply repaid for my trouble, and I may add that it is a pleasure to me to give details of the process to you in acknowledgment of various hints, &c., I have received from the members of this Society and of other similar bodies.

A SINGULAR COPYRIGHT CASE.

The *South Eastern Gazette* has the following details of an interesting case of piracy, in which the copyright of a duly registered photograph is protected:—

F. PHILLIPS v. J. HILLS.

This was a case of a somewhat remarkable character. Mr. D. Kingsford, barrister (instructed by Mr. S. H. King) appeared for

* Read before the Manchester Photographic Society.

the plaintiff, and Mr. J. J. Merriman, solicitor, of Glasshouse Street, London, for the defendant.

Mr. Kingsford said the action was brought under the 25th and 26th Victoria, cap. 63, and the plaintiff claimed a £10 penalty and the forfeiture of a certain copy or colourable imitation of a copyright photograph which the defendant had made. In August, 1877, an Act of Parliament having been obtained, a new bridge over the Medway was commenced at Maidstone. Shortly before the work was begun, the plaintiff, who was a photographer in Maidstone, took some very careful photographs of the bridge from each side, and it was his intention to enlarge them in some cases, hoping that when the old bridge was pulled down the pictures would be of general interest, and would have a large sale. The photograph in question was taken in July or August, 1877, and shortly after it was taken the scaffolding for the new bridge was put up, and it became utterly impossible to take any picture of the old bridge. The plaintiff registered his photographs, reproduced them in various shapes and sizes, and had a large sale for them, the price being 3s. 6d. each. In March of the present year, the defendant, who was an artist in London, and who appeared to have had a relation in the neighbourhood, thought it would be a good speculation to prepare a painting (produced in court) which was really a copy of the plaintiff's photograph; and from what his solicitor then said, it was the defendant's intention to photograph the picture and sell some of the photographs in the town. The picture was placed in the window of Mr. Martin's shop in Middle Row, and on the plaintiff enquiring who painted it, and stating that it was a reproduction of his copyright photograph, Mr. Martin said that it had been sent by the defendant for exhibition. The plaintiff consulted his solicitor, and, wishing only to protect his rights, desired to have the matter arranged amicably. Defendant, whose cousin had previously admitted that he had sent the plaintiff's photograph to the defendant, consulted Mr. Monckton, solicitor, who called at Mr. King's office, and said that the picture was not really a copy of the photograph, and that his client intended to photograph the picture, and was justified in so doing. Plaintiff, under these circumstances, felt it necessary to bring this action.

A copy of the photograph made by the plaintiff was then handed to the Judge, and the defendant's picture, a large size oil painting, valued at twenty guineas, was brought into Court for comparison. Mr. Kingsford pointed out that the painting was almost an exact reproduction of the photograph, the landscape, buildings, barges, boats, and general details being the same. The sky of the picture was of course different to that of the photograph, while the defendant had introduced another boat into the foreground and the figure of a little boy, who was apparently engaged in piloting a miniature ship from the banks of the Fairmeadow.

The plaintiff was called, and deposed to the facts of the case as stated by his counsel. In answer to Mr. Merriman, he said there was nothing new in the design; the sky was blocked out in the usual way, and the clouds were printed in from a cloud negative.

The registry of the photograph at Stationers' Hall having been proved, Mr. John Hills, the defendant's cousin, was called, and deposed to purchasing a photograph of the bridge at Mr. Burgess Brown's, and sending it to the defendant, who lived at Herne Hill.

By Mr. Merriman: His cousin had commenced to paint the picture some four or five months before he sent him the photograph, and was down at Maidstone sketching about twelve months ago.

Mr. S. H. King, solicitor, of Maidstone, said he believed the three sketches produced were those handed to him by Mr. Monckton. The latter, he had since learned, was not going to act in the matter for defendant.

By Mr. Merriman—The defendant had contended from first to last that this was an original picture.

His Honour having expressed some doubt as to the meaning of the words "colourable imitation" in the Act of Parliament, and remarked that surely a copy must be like the original,

Mr. Merriman addressed the Court for the defence. He contended that the Act only gave a man a copyright in the work of his own genius, and a copyright photograph must be a photograph of something which had been created in a man's own brain. A colourable imitation must be something by which a purchaser might be deceived. Nothing was further from his client's thoughts than to interfere with the plaintiff's photographs; and could it be contended that the defendant's twenty-guinea picture was an invasion of a three-and-sixpenny photograph? It was clear the plaintiff had sustained no possible damage, and he was

prepared to show that the defendant's painting was an original picture, although he had availed himself to some extent, as artists often did, of the plaintiff's photograph.

The defendant, Justice Hills, was then called, and said he made the sketches of the bridge produced some time ago, and he also took some notes, which he had mislaid. The picture he had painted was mainly from his sketches and from the photograph. The details he took from the photograph.

In reply to his Honour, who severely cross-examined him, the witness said he had never stood by the Gas Works and sketched the bridge, but he had taken sketches from other points.

The Judge said he had come to the conclusion that the picture was really a copy of the photograph, but he put it to the plaintiff whether he desired the full penalty to be inflicted, or only a nominal one.

Mr. Kingsford said they did not wish to destroy the picture, but it was forfeited. The plaintiff had no vindictive feelings, but wished to be indemnified. The risk was that if the picture were sold it might be copied.

The Judge—Why not present it to the Museum?

Mr. Kingsford thanked his Honour for the suggestion, and said his client would give the picture to the Museum. The painting would come from Mr. Phillips.

The Judge—Defendant will appear as the artist.

Judgment was then entered for the plaintiff, defendant being ordered to forfeit the picture, and pay a penalty of a guinea and the costs.

Mr. Merriman intimated that he might possibly appeal against the Judge's decision.

NEW PIGMENT PROCESS FOR ENLARGEMENTS.

The *Association Belge de Photographie* publishes a pigment process by Dr. Van Monckhoven, which is especially adapted to solar enlargements. He dissolves wax in benzine, charges a small quantity of cotton with the solution, and applies the latter to a light piece of plate glass. The plate is then provided with a coating of collodion or varnish, and then immersed in water for thirty minutes. It is then taken out and placed flat upon a table, where it is coated with a mixture consisting of a coloured pigment, gelatine and bichromate of potassium, which having become firm, the plate is allowed to dry in the dark. In place of this (in addition to this) Monckhoven usually takes pigment-paper, sensitized in the usual manner by dipping in a solution of bichromate of potassium, places it upon the collodionized surface of the plate—previously moistened with water—rubs it down in order to obtain perfect adhesion, and finally leaves it to dry. The plate is then exposed in the solar camera (enlarging apparatus) by allowing the picture-rays to act, through the plate, upon the film treated with bichromate. The exposure is regulated by the assistance of the photometer. The plate is subsequently immersed in warm water of 30° for fifteen minutes, then in water of 60°, after which the sheet (paper) is detached, and the picture developed in the usual manner. It is then fixed, and a piece of white gelatine paper is finally affixed to the picture by means of the roller. When this has become perfectly dry, the picture is detached. If white gelatine paper be used, which is very brilliant (glossy), the picture will retain its smooth appearance even if it is mounted on cardboard. If, on the other hand, dull-looking gelatine paper be employed, the picture will have the appearance of any ordinary print obtained by single transfer. Relative to this process, Monckhoven declares the exposure of the pigment-film as adhering to the plate to be essentially new. The following advantages are claimed:

1. The netlike appearance of the pictures and the spontaneous insolubility of the chromo-gelatine will be avoided.
2. A perfect evenness (uniformity) of the paper, and a greater durability of the same, are obtained.
3. All draw-backs of the single transfer process, as imperfect adhesion, air-bubbles, and other casualties well known to persons using the pigment process, are successfully avoided.
4. The resulting prints remain perfect, and the pictures are clear and sharp beyond comparison.

INFRINGING PHOTOGRAPHIC COPYRIGHT.

ON another page we print details of a curious copyright case, which recently occupied the attention of the Maidstone County Court. The infringement of copyright in paintings by means of the camera has not been uncommon, and it is generally the subject of much virtuous indignation when discovered and prosecuted. Piracy by painting, victimizing the photographer, is not so common—at any rate, it is not so often found out, and made public. There are many such cases, however, familiar to photographers, in which a photographic study has been minutely copied, and then exhibited as an original picture. One of Mr. H. P. Robinson's photographs was so copied not long ago, the artist's plea being that he merely obtained the details of his picture from the photograph! A somewhat similar plea was put forth at Maidstone in regard to the case we have mentioned. Mr. Phillips, a photographer at Maidstone, took some photographs from different points of an old bridge which was about to be removed, thinking that views of the old bridge would be popular after it was gone. The event justified his prevision, and he secured a large sale. Mr. J. Hills, an artist, living in London, thought the old bridge would make a good subject for a picture, photographic copies of which would sell. Unfortunately for him, he did not produce his picture before the bridge was removed. This was not a serious obstacle, however, for according to the allegation of the photographer, Mr. Phillips, the painter, copied the photograph, producing, indeed, a very good copy, with a sky and some figures added. The copying was denied by Mr. Hills, who alleged that he had made sketches of the bridge before its removal. It seemed to be admitted, however, that the photograph was used for the details. The defendant's counsel made some extraordinary remarks in defence. The Copyright Act, he contended, only gave a man copyright in the work of his genius, and a photograph could not be called the creation of a man's own brain! It was impossible, he thought, that a twenty-guinea picture could be a piracy of a three-and-sixpenny photograph. The old, old story of the inferiority of photography to painting! The counsel was endeavouring to be "wise above what is writ" in his allegation as to the intention of the Act, which, in point of fact, makes no mention whatever of the production of a man's own genius. It simply states that he shall have a copyright in the work of which he is the author, whether that work be a product of genius or not. Fortunately, therefore, it was not necessary to argue the possibility of a photograph being a work of art. The judge, very sensibly, examined the painting and the photograph, and expressed his conviction that the former was a copy of the latter; and as, in this case, the painting was forfeited to the plaintiff, the judge suggested, doubt-

less by way of making the pill to be administered less difficult to swallow, that, instead of claiming the picture, the plaintiff should consent to its presentation to the museum. To this course Mr. Phillips consented, the presentation being made in his name, while the defendant's name will appear as artist. A penalty of a guinea and costs was also inflicted, and so the case closed, probably finally, although the defendant's legal representative intimated a possible intention to appeal against his Honour's decision.

BOISSONAS' RAPID PROCESS.

WE do not, as a rule, feel it to be the duty of a photographic journalist to publish secret formulæ where the inventor prefers to sell his method for a consideration. When, however, we find such formulæ in print in another journal, we should, we fear, be wanting in fairness to our readers if we failed to give them the benefit. M. Boissonas, whose rapid process is beyond a doubt valuable, has received injustice before in the publication of an incorrect formula, the credit of its worthless falling upon his shoulders. We find in the *St. Louis Practical Photographer* the following, purporting to be a letter from M. Boissonas giving details of his process to a friend. We reproduce it *verbatim* for what it may be worth:—

The *Practical Photographer* says:—We give below the great secret of the above process which we received from a friend who procured it from the inventor himself:

"Dear Sir,—In answer to your kind letter, giving to you my last improvements, and begging you, after having tried them, to write me what for difficulties or results you obtain, in order to try to help you as much as possible to arrive to the extreme rapidity which I obtain regularly, I do so. I employ gun-cotton, high temperature, from Mr. Guilleminot, No. 6, Rue Choron, Paris, which is very good.

Gun-cotton	10 to 12 (10 is enough)	
Alcohol	400	} 900 cent. cubic.
Ether	500	

I make solution 10 salt, 100 alcohol, let stand, or filter, and take from the clear solution—

Iodine of ammonium ..	45 eub. cents.
Iodine of cadmium ...	40 "
Double bromide cadmium ammonium ...	35 "

In full 120.

"For to do the double bromide of cadmium and ammonium I weigh 6 grammes bromide of cadmium, 4 grammes bromide of ammonium, in full 10 grammes; salt for 100 cent cubic, that quantity of iodizing solution for the over given solution of normal collodion it gives in full.

Cotton	10 grammes
Alcohol	500* "
Ether	500 "

Or very good also—

Iodine of ammonium	25
" sodium	20
" cadmium	40
Double brom. of eadmium ammonium...	35

120

Silver bath	100 grammes
Distilled water	100 "
Iodized with 5 drops of a solution in water—	
Of water	100
Iodide of potassium	4
" cadmium	5
Iod. tincture	1

110

* From which 100 cubic cent. from the iodizing solution.

" Make aside a solution of—

Acetate of copper	100	} 10 per 100
Water	1000	

" Acetic acid enough for to aid to the dissolution, boil, let cool, filter, keep in bottles.

" You make so your developer. In a bottle you put—

Water	900
Sulphate	50

You dissolve and add—

Acetic acid... ..	20 to 25 cub. cents.
Solution of acetate of copper	35 to 40 "
Alcohol	30 "

" Could veil immediately, will be better the afternoon or the day after; wants to be tried for the most favourable moment.

" Kept itself good four or six days, will become red; can be employed for intensifying with a few drops of nitrate of silver.

Intensifier.

Solution of pyrogallic acid in alcohol	10 to 100 cub. cents.
Water	1000 "
Alcohol solution of pyrogallic	50 "
Solution 10 to 100 citric acid in water	20 "

Employed with a few drops of nitrate of silver.

" Try to keep secret to yourself, and write me often. I shall always answer with pleasure to your letters, and should very much like to converse with you a kind correspondence.

" Tell me from your side what comes to your acknowledging which could be employed or tried favourably in order to overgrow the rapidity.

" I remain for ever yours very truly,

" F. BOISSONAS."

" Perhaps later shall I have still good news to write to you.

" Geneva, August 9th, 1878."

PHOTOGRAPHIC SOCIETY FOR IRELAND.

THE following circular, addressed to Irish photographers, explains the desirability of again making an effort to secure the pleasant intercourse and bond of union provided by a photographic society for Irish photographers. We cordially endorse the appeal, and shall be glad to receive correspondence on the subject.

" DEAR SIR,—The want of a Photographic Society in Ireland having been long felt, the present time is thought to be, for many many reasons, peculiarly fitted for the formation of such an Association.

" There are few amateur photographers who, at some time or other, have not felt the want of the assistance of others, to whom they could turn for help and encouragement in the midst of the difficulties and troubles to which all are subject, which beginners sometimes cannot overcome, and which often become serious to those of more mature experience. This want is admitted to be best supplied by the meetings of a society whose members are solely guided by a liking for their art, which all would be glad to advance by every means in their power.

" In many of the large towns in England such societies exist and prosper, and there can be no real reason why such should not be the case in Ireland.
